Gaskell.—On April 28th, at Ladbroke-grove, W., the wife of John Foster Gaskell, M.D., of a daughter.

Hoffmeister.—On April 23rd, at Sion-hill, Ramsgate, the wife of Cyril J. R. Hoffmeister, B.A. Cantab., M.R.C.S., L.R.C.P., of a daughter.

MacRae.—At Roberts Victor Diamond Mine, Roberts Victor, O.F.S., S. Africa, on April 23rd, the wife of Duncan MacKenzie MacRae, M.A., M.B., Ch.B., of a daughter.

Montgomery.—On April 27th, at Messina, Northern Transvaal, the wife of Dr. W. H. Montgomery (neé Dr. Winifred Muirhead) of a daughter (by cable).

Tate.—On April 25th, at Lower Baggot-street, Dublin, the wife of Captain R. Tate, R.A.M.C., of a son.

MARRIAGES.

Coulter—Pope.—On April 22nd, at St. Michael and All Angels, Bedford Park, W., Robert James Coulter, M.A., M.B., of Newport, Mon., to Mary Catherine, second daughter of the late H. Campbell Pope, M.D., and Mrs. Campbell Pope, of Emlyn-villas, Stamford Brook, W.

Garton—Bryce-Williams.—On April 18th, Wilfrid Garton, M.R.C.S., L.R.C.P., to Eleanor de Burgh Bryce-Williams.

Pringle—Cooper.—On April 23rd, at Lacca Church, Kenneth Douglas Pringle, M.B., to Dorothy Despard Cooper, eldest daughter of Mrs. Cooper, of Lacca Manor, near Mountrath, Queen's County, Ireland.

DEATHS.

Barrie.—On April 25th, suddenly, at his residence, Cliff Lodge, Eldon-street, Greenock, Andrew David Barrie, M.B., C.M., in his 71st year.

Cæsar.—On April 20th, at The Oaks, Pevensey, Sussex, Arthur Augustus Cæsar, late Senior Surgeon, East London Hospital for Children, aged 74 years.

Lyon.—On April 20th, suddenly, at Ingatestone Hall, Essex, George Lyon, M.D., M.R.C.P. Edin.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PSYCHOLOGY OF EXPLETIVES.

IN THE LANCET of Oct. 4th, 1913, p. 1037, we published a note with a few remarks on the psychology of "damn," referring to the frequent use of this word on the stage. Another expletive has now been the subject of recent discussion for a similar reason. It may be that it is really the modern corruption of "Byrlady" "By our Lady," as "Marry" is of "By Mary," or it may have some closer connexion with "Sblood"—"God's blood." Most of these old oaths had some reference to God or some divinity or divine subject. For instance, there were "Sdeath" for "God's death," "Zounds" for "God's wounds," "Od's-bodikins" or "Od's-bobs" for "God's body," and "Od's-pitikins" for "God's pity." "Drat." or "Drot." is derived from "God rot." "Gadzooks" or "zooks" is said to mean "God's hooks," the nails of the Cross. "By gosh," "By Jove," and "Begorra" are well known. "The Deuce" for the Devil or "Deus" or "Zeus" is common. "By Jingo" is said by some to be the Basque "Jinkoa"—"God," and by others to be connected with St. Gengulphus. An odd expletive, used in the eastern counties of England some years back and now obsolete, was "By Jimineezer." This is no doubt "Jimenez" and its abbreviated form "By Jiminy," may yet be heard, but it is one of the expletives which have always been more current in the books purporting to portray the life of the people than in their actual life. The French "Dame," for expressing hesitation or surprise, "Parbleu" and "Morbleu," and the German "Donnerwetter" and "Donner und blitzen," are all appeals to God as the Ruler of the Universe. The psychology as well as the etymology of these expressions is certainly an interesting study.

SAPROPHYTIC EXISTENCE OF TRICHOPHYTON ENDOTHRIX.

To the Editor of THE LANCET.

SIR,—Perhaps the following may interest some of your readers. I have been growing and mounting pure cultures of the above fungi from hairs that have been in my possession over eight years. I know there are some dermatologists who think it probable that ringworm fungi may pursue a saprophytic existence; but does not the fact of growing cultures from these hairs prove that trichophyton fungi live a double life, both parasitic and saprophytic?

I am, Sir, yours faithfully,
Maldon, Essex, April 28th, 1914. CHARLES DIBBEN.

MEDICAL PRACTICE IN SWEDEN.

THE conditions of the Public Health Medical Service in Sweden will be found described briefly in THE LANCET, Vol. II., 1911, p. 244. The standard of medical education is unusually high in that country, and it is not rare for the medical curriculum to last over eight years. A special feature is the importance attached by the authorities to the holding of resident hospital appointments. Medical diplomas other than those of the three Swedish Universities are not recognised, and the foreigner wishing to practise in the country would have to pass its medical examinations. During the last few years there has been a growing dearth of medical men in Sweden, and it is therefore possible that on application to the authorities the possessor of a first-class foreign diploma might be allowed to practise without passing all the examinations usually considered necessary.

THE LONDON SURGICAL HOME.

To the Editor of THE LANCET.

SIR,—In the Obstetrical Transactions for 1865 I find Mr. Baker Brown described as "Senior Surgeon to the London Surgical Home." Can you tell me what "the London Surgical Home" was and what became of it?

I am, Sir, yours faithfully,
Leeds, April 27th, 1914. J. B. HELLIER, M.D. Lond.

⁂ The London Surgical Home for Diseases of Women was established in 1858 at 12, Osnaburgh-place, Regent's Park, London. It was "for respectable females suffering from curable surgical diseases." The surgeon was "Baker Brown, Esq." Mr. Isaac Baker Brown resided at 17, Connaught-square, Hyde Park, and 5, Stanley-terrace, Notting Hill. What became of the Home we cannot trace.—ED. L.

ALCOHOL AND LONGEVITY.

To the Editor of THE LANCET.

SIR,—I was very glad to read in THE LANCET of April 18th, p. 1127, that the question of alcohol and longevity, and the statistics which point beyond cavil to the advantages to health from the practice of total abstinence, as evidenced by some insurance statistics, is not endorsed after a careful survey. The reasons given are entirely in accord with my investigation of the subject, carried on now for ten years. I have found these total abstainers who insure are more careful living men, less excitable in disposition, and do not indulge in such violent games and exercises, or are so fond of adventures where there is an element of danger, as those who partake of alcohol. In brief, the alcohol, if drank in strict moderation, has nothing to do with the statistics, but solely the personal element of the insured person.

A very good and practical illustration, which certainly tends to prove that the moderate use of alcohol makes for longevity, is the case of a very near relative of mine, who died at the age of 84 from influenza. The old lady had always taken her wine or beer for dinner and whisky before going to bed. She had a great belief in virtues of beer, stating it prevented constipation and fermentation in the bowels. She was never ill all her life, and only kept her bed during maternal duties; never had to visit a dentist, the teeth merely falling out as the gum receded, and never wore glasses, reading the papers a week before her death. From long clinical experience I believe that pure beer is a most wholesome beverage, epecially for growing boys and girls.

I am, Sir, yours faithfully,
THOMAS DUTTON.
New Cavendish-street, W., April 23rd, 1914.

◆

Income Tax.—The proceeds of the sale of our correspondent's practice should be credited to capital account, and therefore should not be returned as income for assessment to tax. When he purchases another practice the expenditure will be debited to capital account, and will not be allowed as a charge against the profits of the practice.

Enquirer.—It would be advisable for a patient with granular kidneys and a tendency to glycosuria to refrain from taking a beverage which contains both alcohol and sugar, even in small quantities.

ERRATUM.—In our annotation last week on Kubisagari the reference should have been to the *Revue de Médecine*, not to the *Presse Médicale*. We regret the slip.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced.

In 1914:—
- May 1st–Nov. 1st (Lyons).—International Town Hygiene Exhibition.
- „ 15th–Oct. 15th (Berne).—Swiss National Exhibition.
- „ 18th–21st (London, Imperial Institute).—Victoria League Imperial Health Conference.
- May–October (London, Shepherd's Bush).—Anglo-American Exposition.
- June 8th–10th (Berne).—Seventh International Dairy Congress.
- „ 18th–24th (London, Church House, Westminster).—International Conference on the Blind.
- June–July (Groningen).—University of Groningen 300th Anniversary Celebration.
- July 6th–11th (Blackpool).—Twenty-ninth Congress of the Royal Sanitary Institute.
- „ 8th–10th (Oxford).—Ophthalmological Congress.
- „ 15th–20th (Edinburgh).—Congress of the Royal Institute of Public Health.
- „ 21st–23rd (Chester).—British Pharmaceutical Conference.
- „ 27th–31st (London).—Fifth Annual Session of the Clinical Congress of Surgeons of North America.
- „ 28th–31st (Aberdeen).—Eighty-second Annual Meeting of the British Medical Association.
- Aug. 3rd–8th (London).—Sixth International Dental Congress.
- „ 10th–15th (St. Petersburg).—Twelfth International Congress of Ophthalmology.
- Sept. 7th–12th (Berne).—International Congress for Neurology, Psychiatry, and Psychology.
- „ 21st–26th (Vienna).—Third International Congress on Diseases of Occupation
- „ 30th–Oct. 3rd (Brussels).—Fourteenth French Congress of Medicine.
- Oct. 31st–Nov. 2nd (Berlin).—First Congress of the International Society for Sexual Research.
- Nov. 15th–21st (London).—Health Week. (Under the direction of the Health Week Committee appointed by the Royal Sanitary Institute.)
- (St. Petersburg).—Third Mendeléeff Congress on Pure and Applied Chemistry and Physics.

In 1915:—
- May 31st–June 5th (London, South Kensington).—Sixth International Congress of Social Work and Service.
- Sept. 8th (begins) (Manchester).—Meeting of the British Association.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—(4 P.M., Election of Fellows.) Lord Rayleigh, O.M.: (1) Some Calculations in Illustration of Fourier's Theorem; (2) On the Theory of Long Waves and Bores.—Sir Joseph Larmor and Mr. J. S. B. Larmor: On Protection from Lightning and the Range of Protection Afforded by Lightning Rods.—Mr. E. N. Da C. Andrade: The Flow in Metals Subjected to Large Constant Stresses (communicated by Prof. A. W. Porter).—Prof. E. Wilson: On the Properties of Magnetically-shielded Iron as Affected by Temperature (communicated by Prof. J. A. Fleming).—Mr. G. I. Taylor: Eddy Motion in the Atmosphere (communicated by Dr. W. N. Shaw).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF SURGERY: SUB-SECTION OF ORTHOPÆDICS (Hon. Secretaries—A. S. Blundell Bankart, E. Rock Carling): at 5 P.M.

Annual Meeting.—Election of Officers and Council for Session 1914-1915.

SECTION OF PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart, C. Price-Jones): at 8.30 P.M.

Annual Meeting.—Election of Officers and Council for Session 1914-1915.

Dr. H. C. Ross: The Similarity between the Artificially Induced Figures of Cell Division in Mononuclear White Blood Cells and those Found Occurring in the Blood under Natural Conditions in Pernicious Anæmia.

Dr. E. F. Bashford and Dr. J. A. Murray: Observations on the Mechanism of Cell Division (with kinematograph demonstration).

WEDNESDAY.

SECTION OF OPHTHALMOLOGY (Hon. Secretaries—J. Herbert Parsons, Leslie Paton): at 8 P.M.

Cases:

Papers (at 8.30 P.M.):

Mr. R. Affleck Greeves: Pathological Observations on the Filtration Angle in Some Glaucoma Cases.

Lieut.-Col. Herbert: The Ideal Glaucoma Incision.

Mr. N. Bishop Harman: A Variable Flap Operation for Chronic Glaucoma.

Mr. W. G. Laws: Herbert's Small-flap Operation for Glaucoma.

THURSDAY.

SECTION OF OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—T. Watts Eden, C. Hubert Roberts): at 8 P.M.

Annual Meeting.—Election of Officers and Council for Session 1914-1915.

Specimens:

Mrs. Willey, M.D.: Submucous Fibroid showing Implantation of the Placenta on the Tumour.

Dr. C. E. Purslow: (1) Red Degeneration of Uterine Fibroid with Very Early Gestation; (2) Uterus with Multiple Fibroids and Placenta Prævia.

Dr. J. P. Hedley: Fœtal Bones Removed from the Uterus Three Years After a Miscarriage.

Mr. Joseph Adams: Case of Carcinoma of the Uterus in a Child aged 2½ Years.

Dr. Herbert Williamson: Intussusception through a Gastro-enterostomy Wound Occurring during Labour.

Mr. Clifford White: Volvulus of the Cæcum Occurring in Connection with Labour.

Paper:

Dr. James Young: The Etiology of Eclampsia.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries—W. Essex Wynter, Thomas H. Kellock): at 8.30 P.M.

Cases:

Dr. Clive Riviere: Spleno-myelogenic Leukæmia.

Mr. Sidney Boyd: Splenectomy for Splenomegalic Cirrhosis with Ascites.

Dr. Arthur Hertz: Three Cases of Thomsen's Disease in Members of the Same Family.

Dr. Parkes Weber: (1) Progressive Vertebral Ankylosis (Spondylose Rhizomélique); (2) Specimen from a Case of Spasmodic Stricture of the Œsophagus (cardiospasm) with Fusiform Dilatation above it.

And other Cases.

Short Paper:

Dr. J. Alison Glover: Rupture of an Aneurysm of the Abdominal Aorta in a Young Woman.

RÖNTGEN SOCIETY.

TUESDAY.—Paper:—Mr. L. W. Bragg (Cambridge): X Rays and Crystals.

NORTH-EAST LONDON CLINICAL SOCIETY. Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Dr. Redmond's Motion *re* Library. Clinical Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Sarcoma. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

TUESDAY.—4 P.M., Dr. P. Stewart: Clinique (Medical). 5.15 P.M., Lecture:—Dr. A. J. Jex-Blake: Lardaceous Disease and Tuberculosis.

WEDNESDAY.—4 P.M., Mr. P. Turner: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. L. Evans: Knock-knees.

THURSDAY.—4 P.M., Mr. J. E. Adams: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. H. C. Cameron: The Use of X Rays in the Diagnosis of Disease in Children.

FRIDAY.—4 P.M., Mr. A. Levy: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women and Eye Department.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: *Diseases of the Skin.*

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. H. B. Carlill: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine.

TUESDAY.—*Out-patient Demonstrations:*—10 A.M., Dr. C. E. Zundel: Medical. Mr Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., *Dr. G. Rankin:* Medicine. 4.15 P.M., Sir Malcolm Morris: Skin.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. H. B. Carlill: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Rigors.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. H. R. Prentice: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special *Lecture:—Sir William Bennett, K.C.V.O.*

FRIDAY.—Out-patient Demonstrations:—10 A.M., Dr. C. E. Zundel: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: *Operations.* 2.15 P.M., Sir John Rose Bradford: Medicine. 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—*Out-patient Demonstrations:* 10 A.M., Dr. H. R. Prentice: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——10 A.M., Col. Barry: Radiography.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Gynæcological (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Nose, Throat, and Ear (Mr. H. D. Gillies). X Ray and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. Whiting).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. Dorell).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. G. P. Chappell).

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON), Albert Embankment, S.E.

Lectures in Advanced Medical Subjects:—

TUESDAY.—5 P.M., Dr. H. Maclean: Carbohydrate Metabolism in Health and in Diabetes.

GUY'S HOSPITAL MEDICAL SCHOOL, London Bridge, S.E.

Course of Lectures on Industrial Medicine:—

FRIDAY.—Lecture I.:—Dr. F. Shufflebotham: The Symptoms and *Diagnosis of Lead Poisoning.*

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, Medical School, City-road, E.C.

MONDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Cardiac Department, Dr. Stott: Out-patient Department, Dr. Phear, Dr. S. Thompson. 3 P.M., Wards, Dr. Phear.

Tuesday.—9 a.m., Laryngological Department, Mr. Mant. 1.30 p.m., Department for the Prevention of Consumption. 2 p.m., Out-patient Department, Dr. M. Leslie, Dr. B. King; Operations, Mr. A. Evans. 3 p.m., Wards, Dr. White. 4 p.m., Wards, Dr. M. Leslie

Wednesday.—2 p.m., Wards, Dr. A. Davies; Out-patient Department, Dr. Drysdale, Dr. Kellie. 4 p.m., Wards, Dr. Drysdale. 4.30 p.m., Roentgen Ray Department, Dr. Jordan.

Thursday.—9.30 a.m., Dental Department, Mr. G. Thomson. 10 a.m., Cardiac Department, Dr. Stott. 1.30 p.m., Department for the Prevention of Consumption. 2 p.m., Out-patient Department, Dr. Phear, Dr. S. Thompson. 4.30 p.m. Laryngological Department, Mr. Mant.

Friday.—1.30 p.m., Department for the Prevention of Consumption. 2 p.m., Wards, Dr. Calvert; Out-patient Department, Dr. M. Leslie, Dr. B. King.

Saturday.—10 a.m., Out-patient Department, Dr. Drysdale, Dr. Kellie. 11.30 a.m., Roentgen Ray Department, Dr. Jordan.

TY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, ictoria Park, E.

ourse of Demonstrations for Post-Graduates:—

Wednesday.—4 p.m., Dr. H. Walsham: Demonstration of X Ray Cases.

TIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, ueen-square, Bloomsbury, W.C.

Tuesday and Friday.—3.30 p.m., Clinical Lectures:—Dr. G. Holmes: Differential Diagnosis of Cerebral Tumours.

IE THROAT HOSPITAL, Golden-square, W.

Monday.—5.15 p.m., Special Demonstration of Selected Cases.
Thursday.—5.15 p.m., Clinical Lecture.

ONDON LOCK HOSPITAL, 91, Dean-street, Soho, W.

Special Course of Instruction in Venereal Diseases, for Post-Graduates and Students, with Practical Demonstrations of the Various Methods of Treatment:—

Monday.—Clinics:—1 p.m., Mr. Ryall; 6 p.m., Mr. Gibbs.
Tuesday.—Clinics:—2 p.m., Mr. Lane; 6 p.m., Mr. Paterson.
Wednesday.—Clinic:—6 p.m., Mr. Shillitoe.
Friday.—4 p.m., Lecture:—Mr. McDonagh: The Treatment of Venereal Diseases.
Saturday.—Clinic:—2 p.m., Mr. McDonagh.

OYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

Monday.—5 p.m., General Meeting.
Tuesday.—3 p.m., Prof. W. Bateson: Double Flowers.
Friday.—9 p.m., Prof. K. Pearson: Albinism in Men and Dogs.

OYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.

Tuesday.—7 p.m., Lecture:—Dr. M. S. Pembrey: Physical Games versus Set Exercises.

ANCHESTER HOSPITALS POST-GRADUATE CLINICS.

Tuesday.—Manchester and Salford Hospital for Skin Diseases, Quay-street.—4.30 p.m., Dr. G. H. Lancashire: Eczema and Seborrhœa.
Wednesday.—Royal Infirmary—4.30 p.m., Mr. W. H. Hey: Inoperable Malignant Disease.
Thursday.—Ancoats Hospital—4.30 p.m., Mr. J. Morley: Gall Stones.

UNIVERSITY OF SHEFFIELD, at the University.

Post-Graduate Course on Syphilis:—

Tuesday.—3 p.m., Prof. Dean: Application of Wassermann Reaction to Diagnosis, Prognosis, and Treatment. General Pathology of Syphilis as Modified by Recent Research. Latent Syphilis. Parenchymatous Syphilis. Inherited Syphilis.
Friday.—3 p.m., Prof. Dean: General Principles of Chemiotherapy. The Work of Ehrlich and his School. Relations between Chemical Constitution and Specific Action. Atoxyl and Other Arsenical Compounds. Salvarsan.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editor," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Colonial and Foreign Edition (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from The Lancet Offices, have been reduced, and are now as follows:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given above.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

Sole Agents for America—Messrs. William Wood and Co., 51, Fifth Avenue, New York, U.S.A.

The Lumleian Lectures

ON

SOME MODERN THEORIES CONCERNING HYSTERIA.

Delivered before the Royal College of Physicians of London on March 19th, 24th, and 26th, 1914,

BY J. A. ORMEROD, M.D. OXON., F.R.C.P. LOND.,

REGISTRAR TO THE COLLEGE; CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE.

LECTURE III.[1]

Delivered on March 26th.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—The doctrines of Professor Sigmund Freud on the subject of hysteria and other neuroses have not been generally known in England till within the last few years, since they were at first published in a tentative and disconnected way, and only in German. But lately an American translation of his principal work has appeared, and his theories have been expounded in England by Dr. Bernard Hart, Professor W. Brown,[2] and Dr. David Forsyth, so that doubtless they are familiar to many of my audience. But in view of their original character, of the wide application that has been made of them, and of the keen controversies to which they have given rise, it is necessary that I should attempt some exposition of them.

THE VIEWS OF PROFESSOR FREUD.

They originated, historically, in observations made by Dr. Joseph Breuer, and by Freud himself, some 30 years ago. The first case reported by Breuer was briefly as follows:—

> A young woman under the strain of nursing her father developed a severe hysteria with manifold symptoms. Among these symptoms was a sort of alternating mental condition. Thus at certain times of the day she was excited and had hallucinations; at others she was somnolent, and at others again normal. While in the somnolent phase, a sort of auto-hypnosis as it seemed, she uttered sounds and disjointed phrases which were discovered to relate to previous events of her illness, and it was found possible by suitable encouragement to get her to talk of these events, and to express her feelings concerning them. After such a talk she was always better. Artificial hypnosis was then substituted for the auto-hypnosis, and then further progress was made. She could narrate precisely the conditions which had given rise to particular symptoms, and after that, provided the emotion appropriate to the occasion manifested itself, the symptom in question disappeared. This was called the "talking cure" or "chimney-sweeping," or in more dignified language "katharsis."

Summary of Earlier Conclusions.

This method of treatment was applied by Breuer and by Freud to other cases, and from a study of them were derived their first conclusions about hysteria, which may be summarised as follows:—

1. That a hysterical symptom may originate from some disagreeable occurrence, the memory of which is still active, though it has passed from the patient's consciousness.

2. That the symptom can be cured if this memory can be revived in consciousness, and if the patient can be brought fully to relate the occurrence and to express the emotions to which it gave rise.

3. That the reason why the patient has forgotten the disagreeable occurrence which has so affected him—the mental trauma, as it may be called—may be of two kinds: Either (*a*) because when it arose he was in a condition of inattention to his surroundings, a sort of day-dream or state of incipient double consciousness. These states, which Breuer calls "hypnoid," he considers to be common in hysterical patients. In genuine traumatic hysteria the mere shock or fright may produce such a state *de novo*. Or (*b*) because the memory of the occurrence is so disagreeable to the patient that he has voluntarily banished it from his consciousness. The hysteria has then arisen by way of "repression" and is designed to protect the patient from objectionable memories. Such hysteria by repression is called by Freud a "defence-neurosis," and it is apparently the only kind of hysteria which he now recognises.

4. What is the relation of the hysterical symptom to this repression of the memory or idea? The answer is that though the patient may successfully banish from his consciousness the disagreeable idea, yet he cannot thus rid himself of the emotion which attends upon it, the "affect" as it is technically termed; and this would remain as a source of distress were it not that hysterical patients have the faculty (so it is said) of directing this emotion into bodily channels and thereby converting the affect into a symptom, such as pain, spasm, paralysis, and the like. But when the original idea, the skeleton in the secret cupboard of the mind, has been dragged out into the light of consciousness, and the emotion stirred by it has been poured forth in words or tears or passionate display, then the symptom which represented the emotion is no longer needed, and disappears. This is cure by "katharsis." It is, as Aristotle said of tragedy, "a purge for the emotions."

Later Development of Theories.

No doubt these views are simple and attractive. One might doubt, perhaps, the universal efficacy of treatment by "katharsis," and one might ask for much more evidence and explanation concerning the supposed hysterical faculty of "converting" emotions into symptoms. Still we recognise the emotional element in hysteria, and we recognise also the relief given to pent-up feelings—by tears, or perhaps by oaths. But such simple statements are very far from representing the theories developed later by Freud. In these latter, it is true, hysteria remains as a type of a "defence-neurosis," based on the repression from consciousness of disagreeable ideas. But this power of repression is elaborated into a mental faculty which forms the keystone of a large system of psychology. Secondly, the simple plan of hypnotism, followed by "katharsis," is replaced by the method of psycho-analysis. Thirdly, the particular class of ideas and events at the bottom of hysteria, and indeed of all neuroses, is declared on the testimony of psycho-analysis to be solely the sexual class.

Now, it would appear that Freud arrived at his larger theories partly by studying dreams (his own and those of his patients) with the aid of psycho-analysis, partly by studying the symptoms of neurotic patients in the same way, and partly (as it seems to me) by sheer speculation.

The "Censor" and the Unconscious Mind.

The object of psycho-analysis is to bring to light ideas which have been lost to consciousness or which, it may be, have never been apprehended in consciousness. For, according to Freud, the greater part of our mental activity is unconscious. There is within our mind a great mechanism or system of the Unconscious, which receives impressions, stores them in memory, and groups them together by association. Moreover, in this same system, or chamber, of the Unconscious are domiciled the emotional elements of our being, appetites, impulses, and desires, which are constantly striving for an outlet in action and in conscious thought. But before they can arrive at their goal they must pass through another stage called by Freud the Fore-conscious or Pre-conscious. Into this stage they cannot pass till they have been brought into conformity with certain standards, rules, and regulations; but once having been brought into such conformity they can pass into the stage of the Fore-conscious, ready to be called up into conscious thought or action. This sounds so obscure that I will venture on an analogy. You are going to pay your respects to Royalty. You gather together without any formality in certain suites of spacious rooms. These I compare with the Unconscious. Going on with the stream you must pass a door, where certain lynx-eyed officials stand, who may require you to correct any error in your costume, under pain of being turned back. Once past that door you find yourself, not indeed in the Presence, but in an ante-chamber, which you may call the Fore-conscious, and ready at the beck of the authorities to be called into the Royal presence, which I venture respectfully to compare to the highest stage, that of conscious thought.

---

[1] Lectures I. and II. were published in THE LANCET of April 25th (p. [illegible]) and May 2nd (p. [illegible]), 1914.

[2] THE LANCET, April 18th (p. [illegible]) and 25th (p. [illegible]), 1914.

Now the standards, rules, and regulations, to which our thoughts must conform before leaving the Unconscious, have been elaborated by the many influences which have been brought to bear on each individual in the course of his life—education, religion, public and social opinion, previous experiences, previous mental conflicts, and the like. Such influences are summarised, I might say personified, by Freud under the title of the "Censor." The Censor determines what thoughts and strivings from the Unconscious shall be allowed to play their part upon the stage of consciousness, or again he can withdraw his licence, and relegate them back to the Unconscious. But there for good or evil they still exist, and it is asserted that by means of psycho-analysis we can find them out.

A great discovery, if only it be true.

The Process of "Free Association."

Now the assumption has to be made that our thoughts are not determined by chance or by our own volition, but that thought follows thought as surely as event follows event in the physical world; and further, that if any occurrence or thought in the past has given rise to a chain of thoughts which eventuates in a symptom or an idea in the present, this chain can be traced back from the present to the past. For contemplation of the present idea will cause an associated thought of the past to arise in the mind, and contemplation of that thought a further one, and so on from thought to thought till the whole chain can be unravelled. This is called the process of "free association." We must emphasise the word "free." It means freedom, not only from external interference, but also from interference from within. For if the unravelling of associations leads to thoughts which do not meet the demands of the Censor they will be repressed by him, so that either they will not rise to the surface at all or else they will arise in a modified, perhaps an unrecognisable, form.

Psycho-analysis.

The actual process of psycho-analysis is much as follows. The patient must give his willing and intelligent coöperation, and for this it will probably be necessary to furnish him with some explanation of the method to be followed. And first he must give a full and detailed account of his symptoms and the history of his illness so far as he can consciously remember it. It is to filling up gaps in this account or to the explanation of particular symptoms that the psycho-analysis is primarily applied. (I defer for the present the consideration of dreams.) For this he is placed in a restful position, on a couch or chair, usually with his eyes closed, and is told to concentrate his attention on the circumstance or symptom under consideration, and to say what thoughts come into his head or what pictures arise before his mind's eye in connexion therewith. His attitude is to be simply one of contemplation; he is not to try to think of appropriate things, nor yet in any way to criticise the thoughts that do occur to him, but simply to let them come, and to tell them to the physician, no matter how trivial, irrelevant, ridiculous, or disagreeable they may seem to be. From the thoughts or pictures thus obtained others will be obtained, and so on, I must not say *ad infinitum*, but until something essential or important has been reached. It is for the physician, I presume, to settle when to stop, and for him also to settle during the process what clues are to be followed up. In most cases, at any rate, a long process of disentanglement of ideas is to be expected; success in which process will depend partly on the facility with which the patient can produce mental pictures, and partly on the skill of the physician in selecting likely lines of research.

Now if, as I should imagine is often the case, the patient says that no thoughts will come, this, according to the psycho-analyst, is due to the action of the Censor. Thoughts are there, and probably important ones, but they are barred because they are disagreeable to him, or lead up to others that are disagreeable. The patient must be assured that thoughts are ready to come, and if by urging or persuasion or any other means he can be brought into a more contemplative and less critical frame of mind, it is said that they will come.

To an outsider it must be owned the situation seems to be peculiar and even to have a touch of comedy. It reminds one irresistibly of the "thinking shop" in the *Clouds* of Aristophanes, where the old country bumpkin Strepsiades is lying on a couch—less clean and comfortable than the couch in a Harley-street consulting-room—and Socrates, who is in vain trying to extort some ideas from the old man's head, says:—

Σω. Οὗτος, τί ποιεῖς; οὐχὶ φροντίζεις; Στ. ἐγώ;
  νὴ τὸν Ποσειδῶ. Σω. καὶ τί δῆτ᾽ ἐφρόντισας;
Στ. ὑπὸ τῶν κορέων εἴ μού τι περιλειφθήσεται.

. . . . .

Σω. οὗτος, καθεύδεις; Στ. μὰ τὸν Ἀπόλλω ᾽γὼ μὲν οὔ.
Σω. ἔχεις τι; Στ. μὰ Δί᾽ οὐ δῆτ᾽ ἔγωγ᾽. Σω. οὐδὲν πάνυ;

. . . . .

Σω. μή νυν περὶ σαυτὸν εἶλλε τὴν γνώμην ἀεί,
  ἀλλ᾽ ἀποχάλα τὴν φροντίδ᾽ εἰς τὸν ἀέρα,
  λινόδετον ὥσπερ μηλολόνθην τοῦ ποδός.

Socrat. Are you not thinking?
Streps. Certainly I am.
Socrat. What was your thought then?
Streps. I was wondering
How much these bugs would leave upon my bones.
(Socrates reproves him and proceeds):

Socrat. Now, are you sleeping?
Streps. No such luck, by Heaven.
Socrat. What have you got then?
Streps. Nothing.
Socrat. Nothing at all?
Streps. Nothing, but what I have in my right hand.

(The real reply is too Aristophanic for translation, and too Freudian.)

(Finally Socrates explains to him the frame of mind desired:)

Socrat. You keep your thought too centred on yourself.
Let it soar freely in the boundless air,
Just like a beetle threaded on a string.

You might call that "free association."

Another difficulty may be that the productions of the patient seem to be utterly irrelevant and meaningless. This, too, is put down to the action of the Censor. Such futilities are supposed to represent thoughts which in their original state he will not allow to pass, and therefore they have been dressed up, as it were, in a fantastic guise and in this way have slipped past the Censor into Consciousness. To utilise them the physician must interpret them in a symbolic sense. This interpretation by symbols is a very important matter, but I will return to it later.

A Modification of the Procedure.

To be complete, I ought to mention here a modification of the process of psycho-analysis introduced by Professor Jung, of Zürich. A long list of a large variety of words is made out. These are read out one by one to the patient, and he is told to answer to each one, as quickly as he can, with the first word that comes into his head in connexion with each word that is read out. The time taken for each answer is noted on a stop-watch, and it is generally found that he is much longer in answering to some words than to others. This tardiness in reaction is assumed to be due to the fact that the word has called up by association some idea or memory that is disagreeable to the patient and which he therefore tries to repress. It indicates, we are told, "a repressed complex." "Complex" seems to me an unfortunate word, but it is used in this connexion to indicate an idea or system of ideas with which is bound up some powerful feeling. Now if the assumption made about the reactions to the test words be correct, we can find out by them the existence of such "complexes," and possibly, from the nature of the patient's replies, make some sort of guess as to the nature of the "complexes." So that, as Dr. Forsyth points out, this method may serve as a useful preliminary to a psycho-analysis, by enabling us to determine what tracks to follow out.

Difficulty of Psycho-analysis.

I believe that the above description fairly represents the process of psycho-analysis as described by Freud and his followers. If it be objected that in this description I have mixed up theory with practice, I reply that that is exactly what they do. Thus any hitch in the process is put down to the action of the Censor, whereas the very assumption of such a Censor is only justified by the results of the process itself. And the same for other assumptions made about it. But let us defer criticism for the present; enough has been said to show that the method of "free association" is not so easy as those terms might imply; indeed, what with the numbers and complexity of the possible trains of ideas, the barriers or "resistances" to their appearance interposed by the Censor, and the distortion of thoughts produced in their struggle for emergence, the psycho-analysis of a case may be a very difficult process. And also a very long one: Freud tells us that one of his cases was unfinished at the end of five years.

Upon data obtained by this method is built up the whole system of Freud—whether principally upon the psycho-analysis of dreams or upon that of cases of hysteria, it is hard to say, for he refers us from the one to the other in a way that is puzzling. But since he tells us that the interpretation of dreams is the "*via regia*" to a knowledge of the unconscious, I must not evade his views on that subject, and must tax your patience while I try to explain them.

Interpretation of Dreams.

We all know the dream as it presents itself to the dreamer—generally a sort of moving picture of persons, things, and situations, a picture which differs strangely from our waking thoughts, but in which nevertheless we can generally recognise fragments of our waking experiences grotesquely pieced together. This Freud calls the *manifest* dream: it is to be sharply distinguished from the thoughts which really prompt it, which he calls the *dream thoughts* or *latent* dream. The manifest dream is a representation of the dream thoughts, but they are so altered and distorted that without interpretation they are unrecognisable. They are there, it is true, but they are jumbled, confused, and symbolised to such an extent that the manifest dream may be compared to a picture puzzle or a hieroglyphic, which needs deciphering to get at the dream thoughts.

How and why does this distortion take place? The "how" involves several processes; and I must mention some of them, since a knowledge of them is necessary for interpretation.

1. An object in the manifest dream may be compounded from several elements in the dream thoughts; this is called "condensation"; just as we may suppose a centaur to be compounded out of a horse and a man, or a mermaid out of a girl and a fish, or, to take words, just as we talk of the "Bakerloo" railway.

2. Allied to this is the process of "over-determination." A number of things in the dream thoughts may converge, or be piled up, as it were, so as to produce one thing in the manifest dream. Say you have been travelling abroad and the night of your return you dream of lions. Perhaps you started from the city of Lyons in France, read a book on the journey about big game shooting, and as you drove out of Charing Cross Station saw the name of Lyons over a tea shop. Thus the lions in your dream were over-determined.

3. "Inversion." The dream may invert the dream thoughts or take them in the wrong order, so that for interpretation it must be read backwards like Chinese. We might dream first of having a son and heir and afterwards of getting married; or a candidate for examination might dream he came out bottom of the class list because he really wished to come out top.

4. "Displacement of values." This means that the importance or the feelings which attach to a particular element in the dream thoughts are in the dream transferred to something else, or suppressed or disguised. In dreams, perhaps in dreams only, we love our enemies. We might adopt a strange child, because we really felt anxious how to support our own. We might ask a crossing sweeper for a cheque, or give a penny to a millionaire. A

young man, says Freud, dreamed that he had a hole in his overcoat and was terribly shocked at it. The rent had really been in something else. In technical language, the "affect" was transferred.

5. Dream thoughts may be expressed in the manifest dream by symbols, whereof the dreamer himself, whether asleep or awake, does not know the meaning.

6. We are further told, though this is less obvious, that just as the dream picks up the happenings of our daily life and weaves them into a sort of drama, so in order to complete this drama it picks up the fancies and day-dreams in which we may have indulged in our waking hours, and incorporates them into the drama of the dream. This is called "secondary elaboration."

All these processes, and others which I pass over whereby the dream thoughts are transmuted into the manifest dream, are called the "dream work." But why should there be any such dream work? What need is there for all this elaborate misrepresentation? The answer given is this. Our dream thoughts are thoughts which in our waking state we do not recognise as desirable, and therefore the Censor rigorously represses them. But when we sleep, the alertness of the Censor, like that of our other faculties, is dulled, and then is the opportunity for such thoughts to crowd into consciousness. Nevertheless the Censor sleeps, as has been said, with one eye open; and therefore the dream thoughts must assume a disguise in order to evade him and get through into consciousness.

For simplicity's sake, I have omitted the consideration of certain types of dream, which are very common, such as dreams of falling, of flying, of being without clothes in the presence of others, and also of the important fact that the physical condition of the dreamer has an effect upon his dreams. About these things Freud has his special views, which will not commend themselves to everybody.

Causation of Dreams.

Why should we have dreams at all? According to the theory we are considering, dreams are caused by the striving of deeply buried impulses towards conscious gratification. This, apparently, is the final meaning of Freud's well-known formula, "the dream is a fulfilment of a wish." Now at first sight that seems a most untenable proposition. We often have dreams that we should be sorry to see fulfilled, and oftener still our dreams seem to have no relation to our wishes at all. But we must consider two points.

First, that the wish is contained in the dream thoughts, and must be sought there, not in the manifest dream where it has been efficiently disguised. Perhaps we may except some of the simple dreams of childhood, which may be understood without interpretation.

Secondly, what does Freud *mean* by a wish? In the earlier parts of his book he certainly speaks of very ordinary everyday wishes as being fulfilled in dreams, such as the wish to obtain an appointment, the wish to meet a particular person, the wish to go on sleeping, or even the following somewhat ludicrous position of affairs. A man dreamed a dream which he said the professor could not interpret as the fulfilment of a wish. Nor could he, until the interpretation occurred to him that the wish in the man's mind was that the professor might be shown to be in the wrong! But later Freud indicates that such banal wishes are not sufficient by themselves to produce a dream unless they can borrow energy from some of the primitive unconscious desires which are always struggling to emerge into consciousness. In his own words, "A conscious wish is a dream inciter only if it succeeds in arousing a similar unconscious wish which reinforces it." And further, though he does not distinctly assert it, yet it is more than once hinted and implied by him that the chief unconscious inciter of dreams is the sexual desire. Thus a most important modification has been introduced into the original simple meaning of the word "wish." Why it should have been introduced is not clearly explained; I presume, however, partly because further and more prolonged psycho-analysis pointed that way, partly because this modification brought the theory of dreams into correspondence with his completed theory of hysteria and neuroses in general. To which theory, Sir, I must now turn again.

Theory of Hysteria.

Hysteria, he says, like the dream, is based on unconscious thoughts which have been repressed or modified by the agency of the Censor, and the symptoms of the disease, like the pictures of the manifest dream, have to be interpreted by psycho-analysis. But these unconscious thoughts have always a sexual basis. Indeed, in Freud's view this is the basis of all neuroses. He makes this sweeping assertion: "In a normal sexual life no neurosis is possible."

This is a great departure from the original theory of Breuer, according to which the psychical trauma, the memory of which gave rise to the hysteria, might be constituted by any disagreeable event; and it sounds strange, in view of Breuer's first case (quoted above), in which the sexual element was conspicuous by its absence. How, then, was this dictum arrived at? So far as I can make out by the persistent and extensive use of psycho-analysis, which showed that when a history was traced back far enough repressed sexual ideas always emerged. At one stage of his investigations, on the basis of 13 cases, Freud stated that the events which started these ideas were actual criminal assaults on the patient in early life. This statement, as you may easily imagine, had to be given up; the stories of the assaults were simply "phantasies" of the patient, which both he and the psycho-analyst erroneously took to be true. The factors originating the hysteria had then to be sought still further back in life. From this necessity, it would seem, arose Freud's theory of sexuality in the infant. This theory is ingenious and interesting, but to my mind improbable and extremely disagreeable. Nevertheless, it holds such an important position in the views of Freud and his stricter disciples that I must ask your leave, Sir, to give the outline of it.

Infantile Sexuality.

The child, contrary to what is generally thought, has sexual feelings long before the age of puberty, indeed, from his earliest infancy. But this infantile sexuality differs from that of the adult in several particulars. It is unconscious, and not recognised by its possessor in any more definite sense than that of a vague impulse which seeks gratification. It has not the definite scope and definite external object that come in later years; and several regions of the body, not one only, can minister to its gratification. It may therefore be called "auto-erotic" and "polymorphous." It has in itself the germs of all adult sexual impulses, not only of those which are recognised as right and proper, but of those which are perverted and wrong. The right adult sexuality has to be evolved from it by severe processes of restriction and repression.

To follow this out in detail would not be desirable in a lecture, but I may give some brief indications of what is meant. When the auto-erotic impulse of the child first turns to an external object that impulse is bisexual; the homo-sexual element in it has to be suppressed, in order that the individual may become normally hetero-sexual. The first external object of the infant's desire—namely, his mother—must wane, lest in later life he be left under the domination of the so-called Œdipus-complex. The outlying regions of his body—skin, mouth, anus—or so-called "erotic zones," which originally helped to gratify his desire, must be suppressed in favour of the proper genital zone. I shall not elaborate these points; most of them are disagreeable, some like the following one are simply ludicrous. Thus we are told that a predominance of the "oral zone" (mouth and lips) is indicated by a persistent habit of thumb-sucking. This is supposed to give the child some kind of sexual pleasure. One would naturally have thought the pleasure was connected with the remembrance of taking food. Such children, says Freud, become as adults "habitual kissers, and show a tendency for perverse kissing, or as men they have a marked desire for drinking and smoking." I hope, if only for my own sake, that this is not true. Yet such according to our modern Struwelpeter is the fate that

> comes
> To little boys who suck their thumbs.

And so on through a whole gamut of vicious propensities—sadism, masochism, exhibitionism, and the like—all of which are said to have their root in the undifferentiated sexuality of the infant. Though what positive evidence there is for these statements I really cannot discover.

The Mental Conflict in Hysteria.

Now the doctrine of hysteria is connected with this doctrine of infantile sexuality in this way. The infant, though sexually minded, is not worried by that fact. He is shielded by ignorance and lives happily in his garden of Eden. As he grows up the stream of his sexual impulses is narrowed and directed into proper channels by education and other influences. But with the arrival of puberty and under the stimulus of physical sexual development the strength of this stream is enormously increased. If the old channels are insufficiently obliterated they may be opened up again, and with such reopening comes the danger of sexual perversions. Add to this the change that has now taken place in his mental outlook; for consciousness is now directed upon the sexual sphere, which was previously hidden, and further, the revelation of it may take place in some sudden or disagreeable way. Then, to avoid the conflict between the stirrings of a natural impulse and the repugnance felt for the distasteful sexual idea, the individual resolves to banish this idea from consciousness. The Censor bans the play. But he cannot stifle the desires and feelings which prompt it. They must have an outlet, and in the case of hysteria this outlet is provided by the "conversion" of them into bodily symptoms.

The Process of "Conversion."

Now in this so-called process of conversion there is much that is not clear to me. It is not obvious why the faculty of conversion should be only possessed by hysterical patients, nor what is its precise mechanism, nor why hysterical symptoms should satisfy desire, nor why, if the desire is always the same—namely, sexual—the symptoms that satisfy it should be so manifold. To meet this last difficulty we may perhaps introduce a further statement of Freud. He says that hysterical people have the habit of indulging in "phantasies"—that is, day-dreams, reveries, or castles-in-the-air. The content of these day-dreams is generally (so he says) erotic, in women always so. To the desire that prompts them these phantasies stand in the same relation as does the manifest dream to the dream thoughts, and like the manifest dream they have to be interpreted by psycho-analysis. It is these manifold phantasies which are converted into the manifold symptoms of hysteria. Thus, the parent of the symptoms is the phantasy, and the parent of the phantasy is the original sexual motive; or if you wish to connect the symptoms more directly with the motive you may use the language of the stable, and say that they are bred out of Fancy by Desire. The whole thing sounds very hypothetical, and we are told, indeed, by Freud that the relation between the symptoms and the phantasies is a complicated one and only to be understood by psycho-analysis.

Summary of Theory.

I will endeavour now to make a short summary of this complicated theory of hysteria.

The infant has sexual feelings, inchoate, indeed, and unconscious, but so extensive and generalised that the germs of all adult sexuality, normal and abnormal, exist therein. Gradually to restrict this infant sexuality, by damming up undesirable tendencies, or by directing them towards other than sexual objects, such as the arts, poetry, and the manifold objects and ambitions of life, is the work of education and of the higher human faculties. But when in the course of physical development sexual ideas and aims press themselves to the front a struggle ensues between these opposing forces. "The flesh lusteth against the spirit and the spirit against the flesh." Certain individuals terminate this struggle by forcibly banishing the offending sexual idea from consciousness. But it continues to exist in the "unconscious"; and, moreover, the "affect," the emotion or feeling connected with it, cannot be thus banished. This "affect" is then dealt with by "conversion," which means that an outlet is provided for it into bodily channels, and thus arise the bodily symptoms of hysteria. So hysteria is called a "defence-neurosis" because it shields the patient from distasteful ideas and the feelings aroused by them.

There are other defence-neuroses, according to Freud; for instance, that which is known as the "compulsion-neurosis," which embraces apparently such conditions as imperative ideas and the majority of "phobias." In these, as in hysteria, there has been repression of an unpleasant idea, but the "affect," instead of being converted into a bodily symptom, remains and attaches itself to some innocent and otherwise unimportant idea, and from that vantage ground still torments the patient's consciousness. Paranoia is said to be also a defence-neurosis, but with a different mechanism.

All these diseases have a mental origin; they are "psycho-neuroses." There are others, simple neuroses, the mechanism of which is principally physiological. Among these Freud places neurasthenia, using the term, I presume, in a limited sense, which he asserts (on what evidence I know not) to be due to self-abuse, and the so-called "anxiety neurosis," which he ascribes to insufficient sexual gratification and particularly to coitus *interruptus*. To these neuroses, which stand outside his theory of hysteria, he does not apply psycho-analysis; and this is odd, because he applies it to almost everything else with a persistency which sometimes lands him in the ridiculous.

What Evidence is There?

The author of this theory which I have been endeavouring to expound, Professor Sigmund Freud, has devoted many years to the elaboration of it; he has urged it with admirable ingenuity, and with a wealth of illustration which cannot be reproduced in a sketch like the present; he has extended it over a wide psychological area, ranging from the masterpieces of literature to the happenings of everyday life; and as regards the therapeutics of the psycho-neuroses he seems to be regarded by some physicians as a sort of Moses who points the way to the promised land. Small wonder, then, that he has an enthusiastic following; small wonder, too, if you regard the content of his doctrines, that there are rebellious physicians among us, who say with Korah and his company, 'We will not come up."

Now let us admit freely that the theory incorporates some factors which are *veræ causæ*, and not imaginary. Repression of primitive instincts and desires, and of many other motives, must go on in any civilised or moral person. The strength of the sexual motive and the need for government and occasional repression of it cannot be denied. The doctrine of "conversion of the affect," though very hypothetical and vague, yet recognises the large part played by emotion in hysteria, and tries to account for the bodily manifestations of that disease. But these are generalities; to prove an elaborate theory like the present, more precise evidence must be called. What evidence is there?

The answer made is, the evidence derived from psycho-analysis; and those who presume to doubt the validity of this evidence are told pretty plainly that it is beyond the criticism of those who are not themselves experts in the method. They are reminded that histological questions can hardly be discussed except by microscopists, nor chemical problems except by those who have worked in a laboratory. But the parallel is not exact, for it is the method itself of psycho-analysis that is called in question—a method that involves many uncertainties and many assumptions. Outside criticism must therefore obtain a hearing, unless psycho-analysis is to become a purely esoteric cult.

Critical Remarks.

The method, and indeed the whole of Freud's theory, presupposes a determination in mental phenomena as strict as that in the physical universe, so that one thought follows another thought as surely as event follows event. Those of us who are the most steeped in physical science will be the most ready to assent to this. But I doubt whether the average man will endorse it as a universal truth; he will refuse to accept such a dreary fatalism. And indeed the semi-personified Censor of Freud seems a little inconsistent with it, he reminds one too much of those old-fashioned entities, Conscience or Free Will. But let this pass.

Then psycho-analysis professes to take present thoughts, symptoms, or dreams, and to follow them up through a series of past thoughts to those which have been long forgotten, or which, perhaps, never entered into consciousness at all. Is this possible? Only, I imagine, within narrow limits. Any one of us may have occasionally caught himself thinking of something, and, wondering how it came into his head, may have rapidly run back over his thoughts and found what started them in the present direction. But this is a process undertaken at once, concerning recent thoughts, which have been in consciousness, which have patent connexions with each other, and which are revived by conscious effort. Matters may be very different in psycho-analysis. The process may have to be carried back over many years, perhaps to the thoughts and desires of infancy. The successive pictures that arise in the patient's mind may have no apparent connexion with each other—at least, he is not encouraged to look for any. The thoughts which we desire to unearth may have never been present to consciousness at all.

May we not justly doubt whether the things which come into the patient's head during examination really represent the thoughts he had long ago? All sorts of things may have happened in the meantime to obscure the original thoughts and to start different associations. His circumstances now are different to what they were then. And at least there is one new circumstance of the greatest importance, that is the presence and influence of the operator.

For in any but the simplest cases the operator will have to search among the patient's thoughts for clues to the riddle of them, and must form guesses and working hypotheses about the answer to this riddle. He can hardly avoid guiding the patient, consciously or unconsciously, in the direction of these guesses, especially if the patient be a quick-witted neurotic ready to divine the direction in which he is being led. In such a case the free association is no longer free.

There is a still greater danger to freedom when the patient's thoughts have to be interpreted by the operator. This must be done when they appear trivial or absurd or without bearing upon the subject in hand. Now to trace out the effects of the processes which have been described as "dream work"—condensation, inversion, transposition of "affects," and the like—evidently leaves much to the predilections of the operator, even if we assume Freud's canons about dreams to be correct. But how much more is left to him, when interpretation by symbols is employed? You may gather this from Freud's own words:[3] "In the symbolic interpretation of dreams the key to the symbols is arbitrarily chosen by the operator." How arbitrary this choice may be we learn from his chapter on the Material of Dreams. He says: "When one has become familiar with the abundant use of symbolism for the representation of sexual material in dreams, one naturally raises the question whether there are not many of these symbols which appear once and for all with a firmly established significance like the signs in stenography, and one is tempted to compile a new dream book according to the cipher method." (Such a lexicon of dream language has actually been prepared.) Then follow illustrations in which a whole variety of common objects are thus interpreted, regardless of the fact that they might just as well be interpreted some other way. Why should you think that a staircase means coitus or that a lady's hat means something grossly sexual? or why, if you think so, should you tell her so? Yet this has actually been done. And when Freud says: "There is no series of associations which cannot be adapted to the representation of sexual facts," one may reply—"of course, if you are determined to adapt them that way." In another of his writings[4] he says, "He who can interpret the language of hysteria can understand that the neurosis only deals with the repressed sexuality." One strongly suspects that the meaning of that language was invented by the interpreter himself.

---

[3] Interpretation of Dreams, Brill's Translation, pp. 235, 257, 316.

I know that it has been said, in relation to this aspect of the question, that by sexuality Freud means something very large—that is to say, all kinds of emotions which can be connected with or find their root in the sexual sphere. Such a meaning may indeed be necessary to give to his theories that wide scope and extension which he desires. But the bedrock of his theories and of psycho-analysis as practised by him is sex in its barest and least attractive form. Let anyone read the "Interpretation of Dreams" and the "Three Contributions to the Sexual Theory" and judge for himself.

Again, it is said that the sexual factor is unessential and can be omitted from the new psychology. Professor Jung[5] appears to be discarding it as fast as he can. For sexual desire he substitutes desire in general, "*élan vital*," innate energy. When in the battle of life the energy of the individual meets insurmountable obstacles it turns back, or "regresses," towards the phantasies of childhood, and develops from them neurotic symptoms. The initial difficulty is the present obstacle, and not in the infantile past. This may or may not be true, but it is not Freud. Indeed, one wonders how two such distinguished exponents of the psycho-analytic method can have reached by it such different results. Besides, what thin and unsubstantial suppositions have we here been brought to. To adduce them in support of a theory is merely, as Aristotle would say, ἀνάγειν εἰς τὸ ἄλογον.

Therapeutic Value of Psycho-analysis.

There remains the question of the therapeutic value of psycho-analysis. It began as a therapeutic method—the katharsis or confessional treatment of Breuer—but of this we hear little now. Instead, there remains the psycho-analysis by which we hope to discover the paths and the places where the patient first left the road of health, so that by reëducation and appropriate suggestions we can set him in it once again. And if psycho-analysis be necessary for this object, and if it be reliable (about which I have expressed my doubts), I presume it must be used. But I cannot think that it is suitable for general use. The old ideal in therapeutics was expressed in the words "Tuto, cito, et jucundo." We will agree that "jucundo" is the least important point. No doubt Naaman the Syrian did not like the look of the waters of Jordan. Still one must allow that there are many things in one's physical and mental economy which one would rather not expose to view. Were I being treated for dyspepsia I would rather not see the semi-digested contents of my stomach. It would not give me an appetite for the next meal. And similarly for many things that may be lurking in obscure corners of our minds. Freud chose for his dream book a most appropriate motto, "Flectere si nequeo Superos, Acheronta movebo." And he might have added, on his own showing, that the heart of man is "deceitful above all things and desperately wicked."

The other two points, the "tuto" and "cito," are in this case, I hold, essentially connected. Given a rapid and reliable method of bringing the patient to grips with his condition, and of directing his thoughts into healthy channels, we shall all welcome it. But if we are to go on for weeks, months, perhaps years, with a kind of mental vivisection, teaching the patient the while to revive and study all sorts of forgotten facts and fancies, and perhaps to invent new ones—then I fear the process will simply favour the growth of morbid habits of mind, and in the case of a psycho-neurotic will defeat the very object of treatment, which is to drag the patient out of the stuffy chambers of his own mind into the open air of everyday life.

But putting therapeutics aside, the main outstanding question is whether psycho-analysis can be trusted as a means of investigation. Does it really supply a means of penetrating the arcana of our minds? Is there any corroborative evidence of its value? Freud's whole system of psychology is based upon it—an imposing structure, it is true; but if psycho-analysis fails, an edifice without foundations.

MASSIVE COLLAPSE OF THE LUNGS FOLLOWING ABDOMINAL OPERATIONS.

BY T. R. ELLIOTT, M.D. CANTAB., F.R.S.,
ASSISTANT PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL;
AND
L. A. DINGLEY, M.B., B.S. LOND.,
HOUSE SURGEON TO THE HOSPITAL.

IN the Bradshaw lecture[1] of 1908 Dr. W. Pasteur discussed the nature of massive lobar collapse of the lungs, as contrasted with the scattered lobular collapse that occurs passively when the bronchioles are obstructed by secretion and the alveoli are slowly emptied by absorption of their air into the circulating blood. A familiar example of the latter is seen post mortem in the small areas of collapse in a child's lung with broncho-pneumonia. Massive collapse of the entire lobe of a lung develops, according to Pasteur, under one or the other of two conditions: 1. As the result of complete paralysis of the inspiratory muscles, either the intercostals or the diaphragm. The change is occasionally seen in post-diphtheritic neuritis. 2. As the result of a reflex inhibition of the diaphragm's respiratory movement, which may sometimes occur after an abdominal operation, and so lead to alterations in the lung which closely simulate those of ordinary pneumonia.

In two subsequent papers[2,3] Dr. Pasteur developed with greater precision the clinical picture of such post-operative collapse, and showed clearly the need to distinguish it from post-anæsthetic pneumonia, or even at times from pulmonary embolism. It appears after either ether or chloroform, and may develop at any time in the first week after the laparotomy. In some of his cases there was no sepsis nor consciousness of pain from the abdominal wound, and the symptoms of lung trouble appeared to arise quite suddenly. After a few hours, during which the patient may complain of an uneasy feeling in the chest and show a rising temperature, there is a more rapid development of signs and symptoms. Pain becomes acute in the chest, the face assumes a cyanotic tint, the respirations are accelerated, and the pulse is rapid and feeble. On examination the lower half of the chest on one side is found to be moving but slightly, if at all; its percussion note is dull, and the breath sounds over the dull area are at first weak, but later become intensely tubular with whispering pectoriloquy. The other side of the chest is distended and emphysematous: a condition which may make it somewhat difficult to prove the essential point in the diagnosis, namely, that the heart is displaced toward the area of dulness. This displacement of the cardiac impulse may amount to several inches, and by that the state of collapse is at once distinguished from pneumonia or pulmonary embolism. Hæmoptysis does not occur, but there is generally a muco-purulent expectoration.

---

[4] Papers on Hysteria and other Psychoneuroses, No. ix. The Rôle of Sexuality in the Etiology of the Neuroses (p. 192 of Brill's translation).

[5] Discussion on Psycho-analysis at International Medical Congress of London.

The present paper is written to emphasise the clinical importance of Pasteur's massive collapse, to show that it may occur after spinal as well as after inhalation anæsthesia, and, lastly, to discuss the manner in which it is produced. Chiefly by the kindness of Sir Rickman Godlee, who drew our attention to several examples of this condition in patients under his care, we have seen in the last two years 11 cases. Undoubtedly many more have occurred during that time in University College Hospital, for we did not systematically examine every case of post-operative "pneumonia." All followed abdominal operations, either on the appendix, the gall-bladder, or for gastro-enterostomy, or hernia, and in all the operation had been surgically successful. Two examples may be quoted in detail.

CASE 1.—July 12th: Man, aged 31. Bassini operation for double inguinal hernia under chloroform with Vernon Harcourt inhaler. No preceding cough or expectoration. July 13th: Slight fever and bronchitis developed, the fever lasting eight days until the 21st. July 17th: Feeling well and appetite good. Between 8 and 9 P.M. he complained of a "drawing pain" over the xiphisternum, and at 11 P.M. of pain over the precordium. July 18th: At 2 A.M. the pain lessened, but he became dyspnœic and so cyanosed that oxygen was administered. The pulse rose from 88 to 144, and the respirations from 20 to 64; temperature 101° F. 10 A.M., still slightly cyanosed. Right chest immobile in its lower half, with dull percussion note and absent breath sounds over the lower lobe, where vocal resonance was also lost. Under X rays the heart was seen to be displaced to the right, so that its left border was at the left edge of the sternum. The right lower lobe of the lung was very dark, and the upper lobe was dull. On the left side the magnified shadow of the diaphragm on the screen moved three inches, but only half an inch on the right. Muco-purulent expectoration, $\frac{1}{2}$ oz. in last 24 hours.

July 20th: Right side moving better. Left limit of cardiac dulness by percussion 2 inches to left of sternum. Sharply defined area of dulness over lower four spaces at right base behind, where the breath sounds were now intensely tubular and whispering pectoriloquy was heard exactly as in lung that is fully consolidated. No pain. Respiration 24, pulse 96, and temperature 100°. July 21st: Right side moving perfectly; breath sounds normal. X rays showed the heart to be in its normal position again, though the right side of the diaphragm was still a little restricted in its movement, and there was a little opacity in the right base of the lung above the liver.

The patient never complained of abdominal trouble or pain. The skin incision over the left hernia had gaped a little, but there was no infection.

Here the X ray examination proved definitely the extreme displacement of the heart and the immobility of the diaphragm. Pneumonic consolidation of the lung could not have cleared up so rapidly that tubular breath sounds should be replaced by normal breath sounds in 24 hours, and an opaque lung become translucent to X rays in three days. It is certain that the lung had collapsed, and the initial absence of breath sounds followed by their augmentation to a tubular character suggests that at first the bronchi also were closed. When the bronchi opened, the breath sounds naturally sounded tubular owing to their conduction through collapsed lung, while later they assumed the normal vesicular type as the alveoli became fully aerated.

CASE 2.—A healthy young man, 23 years of age, who was accustomed to play Rugby football, and therefore presumably had sound lungs, was admitted to hospital with all the features of an acute appendicitis of 36 hours' duration. Examination of the chest before operation found lessened movement at the right base, normal percussion note, but some weakness of the breath sounds; there were no adventitious sounds. The cardiac impulse was easily found in the normal position, $3\frac{1}{2}$ inches from the mid line. Temperature 100° F., pulse 96, and respiration 24. Not X rayed.

Spinal anæsthesia, the exact height of which was not recorded, was produced by stovaine, and a gangrenous appendix was removed from the outer side of the cæcum. The abdominal wound was closed except for two tubes and a gauze plug. 36 hours later the temperature had risen to 100·2°, the pulse to 104, but the respirations remained at 24. Moist sounds were heard scattered over both lungs. Ten hours later the patient began to suffer from shortness of breath, and for about an hour his respirations numbered 40, with pulse 116 and temperature 102°. During this hour he suffered discomfort, but had no real pain or cyanosis.

In the morning the chest was examined. By percussion the left limit of cardiac dulness was only half an inch to the left of the sternum (verified by Sir Rickman Godlee), and the cardiac impulse could not be localised, though auscultation placed it to the right of the sternum. The right side of the chest was dull up to the fourth rib, while vocal resonance and breath sounds were both much weakened. The sputum was thick and muco-purulent. In four days the heart had returned to its normal position, and the signs had all vanished from the right lung. The abdominal wound drained well throughout, and the temperature became normal on the tenth day after the operation.

Since an X ray examination was not made, it remains uncertain whether the collapse was due to inhibition of the diaphragm or to paralysis of the intercostals by the stovaine; but it is not probable that the latter effect would have been produced on one side only. On theoretical grounds one might have expected that spinal anæsthesia, reaching up in all probability to the third or fourth intercostal space, would have blocked for some time the sensory impulses from the abdomen which are supposed to cause reflexly the inhibition of the diaphragm.

A feature common to these and all our other cases was the presence of muco-purulent expectoration, often in abundance and in three instances of a slightly offensive odour. This we regard not only as a point of diagnostic importance, since it is unlike the sputum of pneumonia, but also as good evidence of the nature of the changes within the lung that induced the collapse. The cause of such infective bronchitis after ether or chloroform inhalation may easily be conjectured, but it is odd that it should have developed also in the patient with spinal anæsthesia.

The Nature of the Change.

The teaching of the earlier pathologists established the belief that the alternating areas of collapse and emphysema in the lobe of a lung affected by bronchitis are caused by the bronchial plugs, which either act as ball valves, allowing the air to escape but not to enter the alveoli, or close the air way altogether so that the alveoli collapse as the air imprisoned within them is gradually absorbed by the blood. Such collapse is *passive*. Dr. Pasteur argued that his cases should be ascribed to an *active* collapse, due to some deflating force, whether elastic or muscular, which compresses and empties the lungs *in the absence of any obstruction of the air way.* This hypothetical force comes into play when the ordinary inspiratory muscles cease to act and inflate the lung. It is quite distinct from the definite deflating forces of external pressure which lead to collapse with a pleural effusion or a subphrenic abscess. His suggestion was that the first step in the process is a reflex inhibition of the diaphragm, the muscle which is concerned especially with the aeration of the lower lobe of the lungs, and that this reflex is originated in most cases by irritation of afferent nerves from the peritoneum as the result of the operation. Next to this would follow an active deflation of the lung by some force, either muscular and external to the lung, or elastic, that is, internal. The air is supposed to be squeezed out of the whole mass of the lung instead of being slowly absorbed from each alveolus.

Certain facts limit the discussion of these probabilities. In the first place, there can be no doubt that the diaphragm is immobile, and that the failure of its action is associated with collapse of the lower lobe of the lung. The rhythmic movement is inhibited, but whether the muscle itself remains contracted or truly inhibited and relaxed is a question that is unanswered. For various reasons we were unable to examine more than one of our cases with the X rays during the acute attack, and so the position of the diaphragm in general was not ascertained. From the usual increase in tone of muscles in reflexes to deep-seated pain or inflammation, it would be natural to assume that the diaphragm would be fixed rigidly in slight contraction, only its rhythm and not the muscle tone inhibited. That is the condition around joints, or over local peritonitis, and probably, too, in the immobility of the intercostals caused by pleurisy. The point is of some importance, because complete inhibition of the dome of the diaphragm on one side would allow the abdominal pressure to tell directly upon the base of the lung and supply a slight deflating force.

Not only the condition of the muscle, but the source of the reflex is uncertain. As a rule the collapse occurs on the same side as the abdominal incision, so that it might be assumed to originate in the abdomen. Yet the condition is seen in cases where the patient has had no consciousness of abdominal pain. Moreover, rigidity or inhibition of the diaphragm is not a common reflex from pain in the abdomen. We have X rayed before operation several cases of appendicitis, simple, gangrenous, with local abscess, and with general peritonitis. In some of these the abdominal wall showed local rigidity, but in all the diaphragm was moving equally on both sides. An acute pleurisy does certainly lead to immobility of the diaphragm as well as of the chest wall, and the same result may be seen with deeper inflammations of the lung, such as gangrene or pneumonia. Further observations are therefore needed to determine whether the source of the reflex concerned in this post-operative collapse lies above or below the diaphragm.

The second point that is certain is the displacement of the heart to the affected side. This was clearly seen under the X rays. The lung was collapsed.

The various conditions which might conceivably expel or exhaust the air from the alveoli and induce collapse of the lungs are as follows:—A. By active compression, through—(i) pressure from outside the lungs; (ii) the elasticity of the alveolar wall; (iii) a hypothetical quasi-muscular contractile power of the alveolar wall. B. By absorption of the air, when the bronchioles are obstructed owing to—(i) inflammatory œdema and secretion; (ii) spasmodic contraction of the bronchiole muscles.

Now such an active deflating force as that of A (i) or A (ii) carries with it inevitably the deduction that the pressure about the lung must be higher on the affected than on the normal side. This is self-evident for A (i), and it is equally certain for A (ii). The elastic tissue of the alveolar wall is expanded by the pull of the negative intrathoracic pressure, and unless endowed with an active power like that of muscle it cannot squeeze the air out of the lung until it is freed from this external distending pull. Consequently, if either external muscular force or internal elasticity is to effect the collapse the intrapleural pressure must be raised from negative towards zero; and in that case the heart would be sucked away from the collapsed side into the contralateral area of greater negative pressure. Actually the displacement is in the opposite direction. Realising this difficulty, Dr. Pasteur suggested that the displacement may be more apparent than real, the left side of the heart being perhaps masked by acutely emphysematous lung and the right heart dilated by pulmonary obstruction. But our examination with the X ray proved the displacement to be very real and considerable. The condition must in consequence be one in which the lung collapse is associated with, though obviously not caused by, a tendency to an increase of the negative intrapleural pressure on the affected side; and this naturally explains the displacement of the heart and mediastinum and the acute distension of the contralateral lung. Compensatory emphysema of the opposite lung could not push the heart across into the area of collapse. The displacement must be the outcome of the increased negative pressure, which is caused by the reduction in volume of the collapsed lung and sucks both heart and contralateral lung across to the side of collapse.

The question is whether this can occur without local obstruction of the air passages. The only possible explanation left along these lines is that of A (iii), which supposes the alveolar wall to have active contractile power like that of muscle, and this assumption finds no ground for its support in the facts of present physiological knowledge.

We are therefore compelled to choose B as the greater probability. Local obstruction of the capillary bronchioles, either by muscular contraction or by blockage with secretion, would satisfy all the conditions named in the state of collapse. It has been shown in recent work on the nature of anaphylactic death in the guinea-pig that the bronchiole muscles are capable of such forcible closure that the animal dies in asphyxia. In man incomplete constriction of the bronchioles from various reflexes is probably responsible for the phenomena of asthma. So we may assume that the bronchiole muscles are strong enough to cut off the air entry to the alveoli. But it is most unlikely that they would be excited to such a reflex action locally and cause lobar collapse; nor would the condition be established without a preceding phase of asthma. Hence B (ii) may be set aside, and we are left with B (i) as the last explanation. In all our cases there was the possibility of such local obstruction, for every patient had muco-purulent expectoration before or immediately after the onset of collapse. We regard this as the essential cause of the phenomena, because the tubes are more quickly blocked by secretion when they are deprived of the ventilating current from the diaphragm's action.

Experimentally, the process has been admirably illustrated by the observations of Lichtheim[4] in 1878, which are further discussed in Cohnheim's lectures on General Pathology (Vol. III.). Lichtheim obstructed a bronchus in rabbits by the introduction of a laminaria plug without opening the thorax. As the plug swelled the lung beyond collapsed; and the animals sometimes died from acute emphysema of the contralateral lung, which was so extreme as to prevent the circulation through it, or even to rupture and form a pneumothorax. Collapse did not occur when the bloodvessels to the lung were tied, and so it was clear that the alveoli were closed passively by absorption of their contained air into the circulating blood. The vacuum produced by the absorption of these gases sucks, to phrase it roughly, on the surrounding organs, causing the liver to rise, the heart to be dislocated, and the contralateral lung to become emphysematous. We think that this was the condition in each of the 11 cases of post-operative collapse that we have observed, for in all there were thick muco-purulent expectoration and fever preceding the symptoms of collapse. The immobility of the diaphragm allowed the secretion to block the smaller bronchioles—it would be too imaginative an inquiry to consider a possible inactivity of the ciliated epithelium—and then collapse ensued precisely as when the obstruction was caused by the laminaria plug. The consequent emphysema of the other side and the dislocation of the heart obstruct the pulmonary circulation, partly by kinking the great veins, partly by compression of the inter-alveolar capillaries. Cyanosis results and dyspnœa. The pain may arise from distension of the heart, or more probably from the strain upon the mediastinal tissues (cp. "drawing pain behind the xiphisternum").

Lichtheim's experiments are so complete that we did not desire to repeat them. Some observations were made by one of us to investigate the possibility of such an active collapse as Pasteur postulated in the absence of obstruction to the air way.

In a rabbit and a cat under ether the phrenic nerve was divided on one side in the neck. The animals were kept alive under ether for six hours, the movements of the diaphragm and the transparency of the lungs being observed by X rays before section of the nerve and subsequently. The diaphragm was fully paralysed, and it only showed slight oscillations as the result of the tug transmitted through the central tendon from the other side. No loss of transparency was seen in the lungs. Finally, the animals were killed by clamping the trachea and at once dividing the carotids. All the lobes of the lungs were found to be equally distended with air.

In two other experiments on cats a wider paralysis of the inspiratory muscles was caused by hemisection of the spinal cord at the second and third cervical segments respectively. Intercostals as well as the diaphragm on one side became immobile. Under X rays the chest looked smaller and slightly less translucent on the paralysed side. After intervals of two and three days respectively each animal was again etherised. The abdomen was opened and the paralysis of the diaphragm confirmed by inspection; the cat was then killed and the lungs examined as in the first experiment. No collapse had occurred.

This result makes an active deflation, as the result of simple paralysis of inspiratory muscles, and in the absence of obvious external pressure, seem to be improbable. And, indeed, the fact that the lungs are not found to be collapsed in ordinary post-mortem examinations points in the same way to the unlikelihood of the supposed deflating force. Surgeons have recently divided the phrenic nerve for the purpose of resting diseased lungs. So far as we can discover from the published papers[5] the resulting paralysis of the diaphragm does not cause collapse of the base of the lung when the disease is early and confined to the apex.

We therefore think that so far as our own cases are concerned the most satisfactory explanation is that which regards the collapse as being the result of an inflammatory obstruction of the smaller air tubes. It is true that objections can be raised to this on clinical grounds. Rhonchi and coarse râles are not often heard elsewhere in the chest, so that it is necessary to suppose that the inflammation is confined to the smallest tubes. The expectoration, though not aerated, is muco-purulent and thick, characters that suggest the infection which is confirmed by the microscopic examination. Since the condition develops rapidly, one may suppose that there is considerable œdema of the smaller bronchioles, though inflammation within the alveoli cannot be in any sense massive, because the collapsed lung is so much reduced in bulk. The collapse would be hastened by immobility of the diaphragm, but it should be remembered that such immobility has only been demonstrated after the collapse has occurred, and that it is not certain that the diaphragm is altogether inactive before this moment. Rapid collapse of a lung, when produced artificially by negative suction from its bronchus, has been proved by physiologists to induce a reflex setting of the diaphragm in a persistent inspiratory contraction, and it may be that such a thoracic reflex contributes to the final standstill.

It must be understood that the explanation we adopt applies only to those cases which we had the chance to observe. Dr. Pasteur described a cleaner type in which the onset was rapid, pyrexia succeeded the collapse and lasted only for 24 hours, while expectoration was practically absent. Perhaps this example may have been governed by another mechanism. Our cases all belonged to the group of infective bronchitis.

To recapitulate.—The 11 cases of post-operative collapse which we observed agreed closely with Pasteur's description. One feature he laid little stress on—and that we regard as critical. All had muco-purulent expectoration and fever, 101° to 103° F., preceding the collapse. There is no reason why fever should develop in a simple non-septic case with reflex inhibition and "active collapse." This fever, which makes the resemblance to pneumonia all the closer, is caused by a purulent bronchitis that is perhaps determined by a preceding infection of the air tubes. Together with this some unknown cause, either thoracic or abdominal, produces a reflex immobility of the diaphragm, and as the combined result of these two disorders of respiration the lower lobe of the lung undergoes passive collapse throughout its mass. This may occur at any time in the first week after the operation.

Since the volume of the collapsed lung is much reduced, movements occur to restore the balance of intrapleural pressures and the heart is displaced to the affected side, while the contralateral lung is overdistended. Pain and cyanosis develop when the displacement is rapid and extreme. At first there are immobility, dulness of percussion note, and weakness of breath sounds on the collapsed side, whereas the other may be so hyperresonant as to resemble the state of pneumothorax. Later, as the bronchial air way opens up, the breath sounds become tubular with ægophony and whispering pectoriloquy. All the signs vanish in two or three days if the right diagnosis is made and active treatment adopted. Otherwise the collapse may persist, the infection spread through the lung, and pleurisy or true pneumonic consolidation develop as a complication. The chief criteria are fever, the greenish muco-purulent sputum, and the displacement of the heart. These together give the distinction from pneumonia or pulmonary embolism, the latter disaster being in the worst cases suggested by the acute onset of pain and cyanosis.

The aim of treatment is to open up the lung before infection spreads into its substance. Expectorants are given with potassium iodide; the patient is encouraged to make full inspiratory efforts, especially of an abdominal type, and if possible for five minutes every hour despite pain that may be felt from the abdominal stitches. If the abdomen has been tightly bandaged this impediment to breathing should be slackened. It is conceivable that the worst cases of cyanosis and pain might be relieved by an intrapleural injection of oxygen, in order to restore the balance of volume and push back the displaced heart and the over-distended lung. Fortunately, these urgent conditions are rare, and we have had no occasion to try this method since the possibility of such a line of treatment occurred to us.

TUMOURS OF THE URINARY BLADDER.[1]

BY R. H. JOCELYN SWAN, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON, S.W.

I HAVE chosen this subject because I have found that not only may difficulty arise in the diagnosis of vesical tumours, but there is still a good deal of misconception as to the true nature of many of them. Recent surgical and pathological work has shown that in dealing with tumours in the bladder the difference between innocent and malignant growths is less defined than in other regions of the body, and rather than discuss the usual text-book descriptions I shall attempt to put forward some points which have helped me in my personal experience of these cases, of which I have now records of 58 under my own observation.

Etiology.

Of the etiology of tumours of the bladder practically little is known. It has been asserted that cystitis or some form of chronic irritation of the bladder may predispose to the formation of a tumour in the same way as it may on the tongue or elsewhere; certainly cystitis frequently accompanies a malignant vesical growth, but it is the ulceration of the latter that produces the cystitis. There is no doubt that the presence of bilharzial ova in the bladder is occasionally accompanied by a papillary growth; and it has been maintained by Wendel that workers in aniline dye [illegible] often subjects of bladder tumours owing to some irritable product discharged in the urine. This cause can hardly hold good, as the vast majority of bladder growths commence just above and outside the ureteric orifices, whereas if the irritation of urine were the cause they should be placed where the urine would impinge—namely, just below and inside the ureteric orifice.

Classification.

Tumours of the bladder may be classified according to their histological characters into the following groups:—

1. Epithelial new growths:
   - Benign ... ... Papilloma (villous). Adenoma.
   - Malignant... ... Villous carcinoma. Nodular carcinoma. Epithelioma.
2. Connective tissue new growth:
   - Benign ... ... Fibroma. Myoma. Angioma.
   - Malignant... ... Sarcoma.

Of these tumours, the villous papilloma and the forms of carcinoma are of much greater frequency than the others, which may all be described as rare tumours. I have notes of one case of sarcoma and I remember seeing another operated upon when I was a student, but the others may be looked upon more as pathological curiosities and I shall content myself with a description of the papilloma and the carcinomata.

Villous Papilloma.

These tumours form distinct outgrowths from the vesical mucous membrane projecting into the cavity of the bladder and covered by fragile, villous processes. They may be single or multiple, and may be pedunculated or sessile. They are usually situated about the base of the bladder, above and outside the ureteric orifices or close to the internal urethral orifice. They vary in size considerably, but even when quite small may produce copious hæmaturia; in one case under my care I had great difficulty in finding a small villous tumour which I had seen with a cystoscope even when I had the bladder fully laid open.

The villous papilloma of the bladder has been hitherto regarded as an innocent benign tumour, but it has several characteristics in which it differs from other benign growths. The frequent multiplicity of these tumours, not only in the immediate vicinity of the original tumour but in areas of the bladder which may become opposed to the tumour as the viscus empties, shows a tendency to growth by direct implantation. There is a marked tendency to recurrence of the tumour after removal, either in the area of the original growth or about the previous cystotomy wound, which cannot be explained entirely by an incomplete removal of the primary tumour, but rather by a local implantation at the time of the operation or by some minute growths which had commenced but had not been discovered. I have seen a recurrence of a villous growth in the bladder after nine years, and in two other cases a recurrence occurred in the cystotomy scar in the fundus of the bladder, one after four years and the other after 18 months. I wish, however, to put particular stress upon another feature of these growths, and this is their marked tendency to assume definite malignant characters, not only in the original, but in the recurrent tumours. We have in our museum a remarkable specimen removed by the late Mr. Cecil Leaf of multiple papillomata of the rectum and pelvic colon in which two separate and quite distant tumours have undergone carcinomatous changes, and I suppose similar changes may take place in vesical papillomata. At all events, it is quite frequent for a villous papilloma to remain more or less quiescent for many months or years and then become malignant, or for a recurrent growth to be malignant when the primary operation has been for a pedunculated papilloma, and in which microscopic examination has shown no evidence of infiltration of the base of the tumour.

---

[1] A post-graduate lecture delivered at the Cancer Hospital, Brompton, S.W., on Feb. [illegible], 1914.

However, one must be careful not to fall into the error in mistaking the original tumour for a papilloma when it may have been malignant from the start, and this brings me to the point in the microscopic examination of these tumours—that is, always have the base of the growth examined for evidence of infiltration. In one case under my care I operated upon a patient who had been troubled with hæmaturia for five years at intervals, and first removed an enormous papilloma the size of a large tangerine orange attached by a small pedicle which showed no sign of malignancy on section. Eighteen months later he again had hæmaturia, and I found several small pedunculated growths on the lateral wall of the bladder which I extensively resected, but no sign of malignancy could be detected in any part of it. Nine months later he came to see me, when I found he had an obvious malignant growth infiltrating the cystotomy wound and the surrounding abdominal wall which grew rapidly. I have records of cases in which carcinoma was found in the bladder following operations for villous papilloma after intervals of 8, 4, and 1½ years, and two cases after 1 year, and another in which attacks of painless hæmaturia had been present for five years before any frequency of micturition commenced, and the growth was then found to be malignant. Thus there is good evidence that a villous tumour of the bladder shows a distinct tendency to become malignant, and cannot be looked upon as a wholly innocent tumour, a point which must influence us in our treatment and in our prognosis.

Symptoms.—The chief and often only symptom of villous papilloma is hæmaturia. This may occur suddenly without any traumatism or apparent cause, usually surprising the patient by its appearance, and is often profuse. It may last for one or two occasions of micturition or for a day or so, and usually stops as suddenly as it commenced, to recur after an interval of weeks or months in the same character. In a case under my care the patient had had attacks of hæmaturia at intervals of about three months for 16 years. Three separate and distinct papillomata were removed, and there has been no recurrence up to two and a half years. The blood is intimately mixed with the urine throughout micturition, or if only slight may be more marked in the last few drops of urine. Occasionally it may be so profuse as to clot in the bladder, when flat clots may be passed per urethram. The presence of clots in the bladder may give rise to a certain amount of vesical tenesmus, but apart from this pain is infrequent. In the intervals between the attacks the urine is normal, and it is one of the points of distinction between a papilloma and a carcinoma that in the latter cystitis occurs frequently, whereas it is uncommon in papilloma unless some instrumentation has caused it. There are a few other symptoms which may occasionally be present; there may be a sudden stoppage in the stream of urine during micturition, accompanied by penile pain, from the plugging of the internal urethral orifice by a piece of growth, or there may be aching in the loin due to increased intrarenal pressure from a slight obstruction to the ureteric orifice on that side. Occasionally the kidney may be definitely enlarged, and in one case under my care, in which an enlarged kidney was accompanied by attacks of profuse hæmaturia, I was asked to remove the kidney under the assumption that it contained a hypernephroma. I was able to prove by the cystoscope the presence of a villous papilloma covering the ureteric orifice, and after the removal of this tumour the renal swelling entirely subsided. I have seen this patient recently, and find he has a recurrence of the papilloma in the same position nine years after his operation, but the kidney remains of normal size.

Occasionally small pieces of epithelial tissue may be passed in the urine. These appear as pinkish, gelatinous fragments, showing a villous formation when floating in water. They are not common, although their presence is always suggestive of vesical tumour; but I would ask you to bear in mind that microscopic examination of the surface fragment will give no indication whatever whether it arises from a simple papilloma or from a villous carcinoma.

Diagnosis.—The recurrence of attacks of profuse, painless hæmaturia in a comparatively young patient is always suggestive of vesical papilloma, but it is necessary to diagnose it from other conditions. A renal papilloma or hypernephroma may produce profuse hæmaturia, and the former may cause fragments of papillomatous tissue to be voided in the urine; a renal papilloma is, however, very rare, and hypernephroma occurs, as a rule, after the age of 55 years. In either case worm-like clots from formation in the ureter may be present, whilst their passage usually gives rise to pain simulating renal colic.

Renal tuberculosis may exceptionally give rise to profuse hæmaturia, but will be distinguished by the increased frequency of micturition, pyuria, the frequent slight hæmaturia, and the palpation of a thickened ureter per rectum.

Vesical tuberculosis is almost always a descending infection from a renal focus and will be readily distinguished by the increased frequency of micturition, pain, and pyuria, whilst vesical calculus will be diagnosed from the increase in pain and frequency during movement.

By far the most ready means of diagnosis, however, remains with the cystoscope, for not only can the vesical lesion be determined with accuracy, but the character, size, exact position, and multiplicity of the growth be seen. I prefer to cystoscope these cases during an interval of freedom from bleeding, when the bladder can be more readily examined, but in some cases where the opportunity does not occur it must be done whilst hæmaturia is present. In these cases a medium clear enough to see through can usually be obtained by first washing out the bladder with silver nitrate 1:4000 or adrenalin 1:2000. In some cases of painless hæmaturia it may be an advantage to cystoscope during an attack of bleeding, for should the hæmorrhage be renal in origin this will be seen as well as the side from which it occurs.

A papilloma of the bladder appears as a rounded tumour, covered by some translucent villous processes in which the central vessel may often be seen, varying from delicate, elongated, feathery processes which float about like those of a sea anemone and are stirred by the swirl of urine ejected from a ureteric orifice, to short, stunted, or mere rounded processes presenting a coarsely mammillated appearance These are usually situated about the base just outside the trigonal area, and may be attached by a delicate stalk or be sessile. They frequently hide the neighbouring ureteric orifice, and may be accompanied by smaller papillomata in the surrounding area. Occasionally the growth may attain such a size that the beak of the cystoscope passes into it so that no view can be obtained, as happened in two of my cases.

Treatment.—I have no doubt that in view of the tendency to recurrence and to become malignant, the ideal treatment of a villous papilloma of the bladder is to remove it by a complete resection, including the area of mucous membrane from which it grows. I am sure that the old-fashioned operation of opening the bladder and twisting the growth off its pedicle was not only incomplete, but was frequently followed by recurrence, whilst removal of the growth by a lithotrite or by an operating cystoscope is not radical for the same reason. The bladder after irrigation should be distended and opened in the mid-suprapubic line, and the base may be well displayed by packing a large gauze swab under a broad-bladed retractor at the upper angle of the wound. The use of the Trendelenburg position and of an electric head-lamp greatly facilitates the operation. The ureteric orifice near the tumour is identified, and if close to the pedicle it is often useful to pass a fine catheter into it as a guide. The tumour is then raised from the bladder and a small thread suture passed through the mucous membrane of the bladder on each side of the growth to mark the extent of removal necessary. Slight traction is made on these two sutures, as well as upon the tumour, and an incision carried around the base through the mucous membrane exposing the muscular layer of the bladder wall. After removal of the papilloma, together with a healthy area of mucous membrane, bleeding is arrested and the edges of the incision approximated with fine catgut sutures. In sessile growths exactly similar procedure is adopted, but in these cases a larger area of mucous membrane must be resected, and in one case I was obliged to resect the terminal three-quarters of an inch of the ureter and transplant it into the upper part of my vesical incision, owing to the implication of the orifice in the growth. In another case in which multiple papillomata recurred 18 months after the removal of a large villous tumour, I had to resect a large portion of the lateral wall of the bladder, and this case is of especial interest in that the specimen removed showed no signs of malignancy, but yet a year later the patient had a diffuse carcinomatous growth about the abdominal incision. During the operation the utmost care should be taken to prevent soiling of the operation area by the growth, and it is important to swab out thoroughly the area with saline or weak nitrate of silver solution with a view to prevent *reinfection* taking place. When all bleeding is stopped I sew up the bladder wound with fine catgut, leaving a small drainage-tube in the prevesical space, and drain the bladder by means of a catheter retained in the urethra.

In 13 cases of villous papilloma 11 were operated upon. One died from uræmia three days after the operation; 3 cannot be traced; 3 recurred, one after nine years, one after three years, and one in 15 months. The remaining 4 are free from recurrence after intervals of 7, 5, 4, and 2½ years.

In some cases of multiple growths studded over the vesical surface a radical operation is out of the question, and though these cases are probably malignant in origin an attempt may be made to slough off the exuberant growth by means of daily irrigations with increasing strength solutions of silver nitrate up to 1:500, as recommended by Herring, or by an open operation to remove the growths separately and to cauterise the base with a fine electric cautery point or nitrate of silver.

In cases in which a radical operation is not contemplated symptoms may arise which require treatment. Hæmorrhage may be severe, but is seldom enough to endanger life. In cases of hæmorrhage the patient should be kept in bed, and morphia given with calcium lactate in gr. xx. doses; if the bleeding is not arrested by these means a full-sized catheter should be passed and the bladder gently irrigated with hot saline solution (115°F.) or with hot solution of nitrate of silver (1:5000). In some cases a small quantity of silver nitrate (1:1000) or adrenalin (1:1000) may be run into the bladder and drawn off after a few minutes. Should clotting of blood have occurred in the bladder, the clots should be extracted by a large evacuating cannula attached to a rubber bulb as used after litholapaxy. If there is severe vesical tenesmus, it is probable that cystitis is superadded upon the tumour, and suitable treatment adopted. Suppositories of morphia and belladonna will relieve the pain or a suprapubic fistula may be made.

Carcinoma of the Bladder.

This is in my experience more than three times as common as papilloma (44 to 13). It occurs in different forms in which both the pathological and microscopic characters differ markedly. For purely clinical purposes they may be divided into a papillomatous or fungating group and an infiltrating sessile group. In the former group the tendency is for the growth to exuberate into the cavity of the bladder, forming large masses of soft, friable growth very similar in appearance to the papilloma, but in which the villous processes are more stunted or rounded and more irregular in shape, whilst the pedicle is thicker, firmer, and adherent to the submucous tissue. Microscopically the base shows that epithelial cells are invading the lymph spaces, and later may infiltrate the muscular wall of the bladder. In some cases the surface of the tumour may be devoid of villous processes, appearing as a raised nodule projecting into the bladder, with comparatively smooth surface which may be ulcerated in parts. The base of these growths shows marked infiltration with proliferating epithelial cells. In the infiltrating group of vesical carcinoma the growth presents the appearance of an ordinary epithelioma with a central depressed ulcer surrounded by heaped-up, friable nodules of growth and deeply infiltrating the deeper structures of the bladder wall. The two forms occur with about equal frequency (21 : 23).

As I have stated above, a carcinoma of the bladder may commence in an old-standing villous papilloma or in the recurrence of a papilloma, in which case it usually takes the form of a fungating growth, or it may arise without previous existing disease. It is certainly more common than papilloma, and I am inclined to think that many cases which have in the past been looked upon as villous papillomata were in reality villous carcinomata. This may in part account for the early recurrent cases, and I look with extreme suspicion on any vesical papilloma which is covered with stunted villi or which has any but a very delicate pedicle. Even in the absence of any microscopic infiltration of the base by epithelial elements, I should look upon these tumours as malignant. Possibly I am inclined to look upon these cases as more commonly malignant owing to the number which are sent to this hospital in advanced stages of carcinoma which have been treated elsewhere.

Lines of spread of the disease.—Before we discuss the symptoms and course of carcinoma of the bladder let us for a moment consider the lines of spread of the disease. In the first place a malignant growth may spread in the bladder, small implantation growths arising in the vicinity of the primary tumour or in that part of the bladder wall which comes into contact with it when the bladder is emptied. There is also a distinct intramural spread, the growth infiltrating the muscular coats in the lymphatic spaces to a wider area than that occupied in the mucous layer. At the same time the growth penetrates through the vesical wall and may cause adhesions (and later direct infiltration into) to the rectum, vagina, or small intestine. In one remarkable case of a villous carcinoma in a young man the growth recurred very rapidly after removal, and the patient died in eight months. I made a post-mortem examination and found an enormous mass of growth extending from the bladder and directly invading the recti abdominis muscles; it extended laterally and directly infiltrated the pelvic bones, extending on the left side into the acetabulum, and on both sides bulging through the obturator foramina and invading the origins of the adductor muscles; on the left side it invaded the sacro-iliac joint and the gluteal muscles covering it. No other secondary deposits were found in the viscera or skeleton. This very rapid spread is most exceptional. Finally, the growth may spread by lymphatic extension following the trunks to the glands about both the internal and external iliac arteries, and in this situation may cause pressure upon nerves.

Symptoms.—The symptoms of vesical carcinoma vary somewhat with the character of the growth, and naturally with the extent of the infiltration. Hæmaturia is usually the first sign and may come on similarly to the papilloma as a profuse hæmorrhage, lasting a day or so and then recurring. With carcinoma the intervals between the hæmorrhages are less than in papilloma, and there is a much greater tendency to a more or less continuous slight hæmaturia. Another feature is that the blood is often more marked at the end of micturition, the last few drops of urine being more deeply stained than the earlier urine.

Increased frequency of micturition is another early symptom of carcinoma, coming on at first gradually, both during the day and the night, and increasing until it reaches as often as every quarter or half hour. Increased frequency is always more marked in the infiltrating than in the papillary carcinoma, and may occur whilst the urine remains clear, but is aggravated by the occurrence of cystitis.

Pain is usually present with carcinoma of the bladder. At first it is felt in the suprapubic area when desire to micturate becomes marked, and also in the perineum and terminal part of the penis when the bladder empties. It is also aggravated when cystitis is present, and may in some cases be due to obstruction of the internal urethral orifice by growth or by blood clot. There may be aching in the lumbar region, either from direct obstruction to the ureteric orifice from the growth or to ascending septic infection of the kidney. In later cases in which the pelvic glands have become affected by growth there may be pain along the course of the sciatic, crural, or obturator nerves from pressure.

The urine, apart from the presence of blood, may at first show little change, but as the growth progresses ulceration is produced, and the urine then contains pus, blood, and excess of mucus with the presence of cystitis. Later the urine becomes ammoniacal and foul, and may contain small conical-shaped masses of phosphatic material which has become loosened from the surface of the growth. Small masses of growth may also be passed in the urine, but too much stress must not be placed on the apparently benign appearance of these under the microscope as they are usually pieces from the surface of a fungating growth.

Diagnosis.—In cases commencing with hæmaturia difficulty may arise in the diagnosis. In speaking of the diagnosis of a villous papilloma, I pointed out the great advantage of a cystoscopic examination, which not only shows at once whether the bleeding is vesical or renal in origin, but will also demonstrate in the former the presence of a growth or some other lesion. Of these, tuberculous disease occurs in younger patients, is nearly always secondary to renal tuberculosis, so that distinct evidence is present in one ureteric orifice, the ureter may be felt to be thickened per rectum or per vaginam, and other evidence may be found of tuberculosis elsewhere in the body (prostate, testes, &c.). Bilharzia may cause hæmaturia and a sessile fungating mass in the bladder, but will be recognised by the presence of the characteristic ova in the urine, but the great difficulty may arise in the diagnosis between a simple villous papilloma and a villous carcinoma. In cases in which the tumours show on cystoscopic examination long, delicate, feathery processes springing from a small pedicle, the growth is probably innocent, but when the villi are stunted and rounded, the pedicle short and broad, and the immediate area of the attachment of the pedicle shows elevation or thickening of the vesical mucous membrane, or the surface of the tumour shows a fleshy mammillated appearance, then suspicion should at once be aroused of a malignant tumour. In some cases, owing to the hæmorrhage or to the size of the tumour, a cystoscopic examination may be unsatisfactory and our diagnosis must rest upon the clinical evidence, and I would say at once that the presence of increased frequency of micturition or of pain following micturition is strong evidence of malignancy. Cystitis, apart from any instrumental infection, is very uncommon in benign tumours, but frequent with carcinoma. A further important piece of evidence may be obtained from a careful rectal examination; with villous papilloma nothing abnormal will be felt unless the growth is large, and then only a soft mass in the bladder on bimanual examination; but in malignant disease an increased resistance may often be felt in the bladder base on one side of the middle line, whilst a thickening may often be detected extending outwards towards the pelvic wall from the upper and outer part of the prostate due to extension in the lymphatic system.

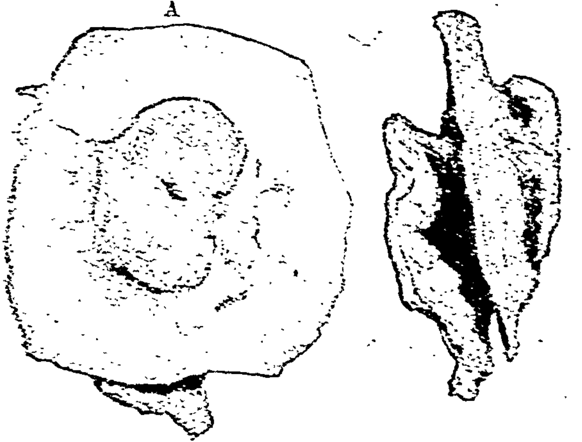
In other cases in which hæmaturia is slight, but in which increased frequency of micturition and pain are the predominant features, the diagnosis must be made from vesical calculus, from prostatic enlargement, and from cystitis. In calculus the pain is more marked at the termination of micturition, and in the absence of marked cystitis the increased frequency of micturition only occurs in the daytime, and is increased by movement. In prostatic enlargement the onset is more gradual and hæmaturia is less common. Pain may be marked in prostatic carcinoma, but in each case a rectal examination will determine the presence of a prostatic tumour. I have had recently two cases under my care which caused some trouble in diagnosis. In the first, a stout gentleman, aged 71, had had increased frequency of micturition for three years together with some difficulty in micturition. Three months before he had had hæmaturia, which had recurred at the time I was asked to see him. I found that he had 9 ounces of residual urine in the bladder, and I was unable to get a satisfactory view with a cystoscope owing to bleeding from the prostatic urethra in passing the instrument. Per rectum there was a very large, soft, adenomatous prostate, for which I recommended removal. On opening the bladder a few days later for this purpose I was surprised to find, in addition to the enlarged prostate, a hard infiltrating epithelioma of the right lateral wall of the bladder, ulcerated at the upper end and too extensive to remove. In the second case a cystoscopic examination demonstrated a nodular, ulcerated growth on the right of the bladder base, but on rectal examination the prostate was found to be slightly enlarged, very hard, nodular, and fixed, extending as a broad infiltration into the bladder base and towards the right pelvic wall. In this case I think the growth was primarily in the prostate with direct spread to the bladder.

In the infiltrating growths the cystoscope shows an ulcerated area surrounded by irregularly placed, raised nodules of growth, and per rectum a hard plaque may be felt in the bladder base.

Treatment.—The treatment of carcinoma of the bladder depends upon the local condition present, the amount of apparent extension of the growth, and the physical condition of the patient. If the growth is small and, as far as can be ascertained, is confined to the bladder, and the patient's condition enough to warrant a severe operation, an attempt at complete removal should be made. These conditions are but rarely fulfilled, as the cases are so often seen when extravesical spread has already occurred that any attempt at radical removal is unjustifiable. Should, however, an attempt be made to remove the growth the bladder should be opened above the pubes and the area surveyed. When the exact condition has been determined, a small bougie should be passed into the ureter if the growth approximates the latter, and the vesical incision extended into the peritoneal cavity and the intestines packed off by flat swabs, the high Trendelenburg position helping in this. The steps of the resection depend upon the position of the growth, but in all cases the bladder wall must be removed wide of the base of the tumour. If the ureteric orifice is placed within the area required to be resected I have no hesitation in removing it. The incision should be deepened on either aspect of the ureter and the latter identified in the extravesical tissues and separated. After the whole growth and surrounding area of bladder wall have been separated the ureter is divided and the proximal end brought up and sutured into the upper angle of the deep vesical incision by three sutures of fine catgut before the wound is approximated. I have had occasion to remove the terminal portion of the ureter in six cases, once for epithelioma, four times in villous carcinoma, and once in papilloma, and only in one of these cases has there been any aching in the loin following it. I never completely close the suprapubic wound after the removal of a malignant growth, but prefer to drain the bladder for some 10 to 12 days by a rubber drainage-tube.

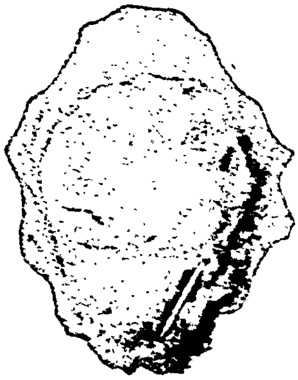
In some cases of multiple malignant tumours radical resection cannot be performed, but the condition may be considerably alleviated by the local removal of each fungating growth and the cauterisation of the pedicle. For some cases complete removal of the bladder after implantation of the ureters into the rectum or vagina or after bilateral nephrostomy has been recommended, but I have no experience of it, and the statistics of recorded cases are by no means encouraging. In my own cases, in which 23 were epitheliomatous, I operated upon seven, but in only two was I able to complete a resection. In one case of an apical epithelioma (Fig. 1) there was no recurrence in the bladder, but recurrence took place in the pelvic and lumbar glands in 18 months, accompanied by nerve-pressure symptoms, and the patient eventually died. In the other (Fig. 2), in which I removed the growth with the terminal portion of the ureter, recurrence occurred in the pelvic glands in 20

FIG. 1.



Epithelioma of anterior wall of bladder, resected with whole thickness of bladder wall. A, Surface view. B, Lateral view showing raised epithelium with subjacent muscular and peritoneal layers.

FIG. 2.



Epithelioma of base of bladder, resected with terminal end of ureter, latter transplanted. A rod is passed into ureteric orifice.

months, soon followed by metastatic deposits in the liver, death ensuing in 28 months after the operation.

In the villous carcinoma the prognosis is more hopeful. In my series of 21 cases, 5 were too extensive for any operation owing to the extent of the extravesical infiltration, but in 6 I performed a palliative operation to remove the exuberant masses of growth in the bladder either for hæmorrhage or for obstruction. In each of these recurrence took place rapidly. In the remaining 10 cases I resected the growths widely in the absence of any apparent extravesical spread of the disease, and in 4 was obliged to resect a part of the terminal portion of the ureter. Of these 4, 2 are alive and well after 4 years and 2½ years, but the two others recurred after 1 year and 1½ years with glandular deposits. In the remaining six cases, 2 are alive and well, 1 after 4 years and 1 after 1 year; 2 rapidly recurred in the bladder, and 2 cannot be traced. In one of the recurrent cases of this last group I operated a second time, removing a large piece of bladder wall, but recurrence again occurred in a year, and the patient refuses further operative treatment.

In cases of carcinoma of the bladder in which radical treatment cannot be carried out, it may be necessary to provide treatment for the more urgent symptoms. If hæmaturia is severe similar treatment to that recommended in villous papilloma should be tried—namely, complete rest under morphia, with ergot and calcium lactate in large doses; irrigation of the bladder with hot silver nitrate solution 1 : 5000 at 115° F., or with adrenalin 1 : 2000. If there be clotting in the bladder an attempt should be made to extract it by an evacuating cannula and bag, and should the hæmorrhage not yield to these measures a suprapubic cystotomy should be done, any fungating growth removed, and the base treated with the cautery.

Pain and increased frequency of micturition may become very distressing in vesical carcinoma, and often in part are caused by accompanying cystitis. Sandalwood oil and urinary disinfectants should be given, and the bladder irrigated with hydrogen peroxide (one volume) or weak nitrate of silver solution; suppositories of belladonna and morphia or a small enema containing tinct. opii ♏ xx. may relieve it. In several cases under my care I have opened the bladder above the pubes, removed any fungating growth, and provided a permanent suprapubic fistula with great relief to the unfortunate patient.

Finally, I have tried the effect of placing a tube containing 50 mgrm. of radium into the bladder for periods of from 12 to 24 hours, but I cannot say that I have found any relief from pain from its use nor any diminution in the size of the growth. The bladder is often so intolerant that the presence of the tube causes pain, but I think further trial should be given to radium in these cases so that experience may be gained in the proper dosage, &c. We must not expect radium to do all the wonders in cancer that the lay press would have us believe, especially where the malignant process has spread beyond the bounds of its original focus, but in a few cases of carcinoma in other regions I have undoubtedly seen good results from it, and so shall persevere with it when the opportunity arises and when radical operative measures are contraindicated.

Wimpole-street, W.

DEATH FROM HYPERACUTE STREPTOCOCCAL INFECTION (STREPTICÆMIA)

FOLLOWING RADICAL REMOVAL OF CERVICAL TUBERCULOUS GLANDS WITH SINUSES.

BY GEOFFREY JEFFERSON, M.S. LOND., F.R.C.S. ENG.,
LATE SENIOR HOUSE SURGEON AND ASSISTANT ANÆSTHETIST, MANCHESTER ROYAL INFIRMARY; AND DEMONSTRATOR OF ANATOMY IN THE UNIVERSITY OF MANCHESTER.

THE two cases which I report below are of sufficient interest to have attention drawn to them. They present a possibility of which I had been unaware—namely, death within a few hours of radical removal of tuberculous glands. Moreover, I have been unable to find any reference to such an occurrence in the literature, and though I have since heard of such cases in conversation they were regarded as very mysterious and the true import of them had not been appreciated. I regret that only the second case was adequately inquired into after the warning given by the first case, but the clinical details corresponded so closely in both that one cannot but believe that they were both victims of the same disaster.

CASE 1.—The patient was a male aged 1 year and 10 months. He was a very big boy for his age, fat and chubby, but a little rickety. There was a family history of consumption on the father's side. Six and a half weeks before admission to the Victoria Hospital for Children, Chelsea, lumps appeared on the left side of his neck in the occipital region. These went down of their own accord. One week previously a lump had appeared in the upper cervical region of the same side. This lump became red and inflamed owing, his mother said, to a knock received in bed. On admission there was a red fluctuating gland adherent to the skin in the left upper cervical region. There were one or two large glands deep to it. On Oct. 21st, 1912, the gland was incised, but was found to contain nothing but soft, grey, tuberculous-looking material without caseation. It was scraped out and this gland was found to lead into a deep one, which was similarly treated. The wound refused to heal, and protuberant pale granulations sprouted from it. After nearly a month of trying to accelerate healing a radical operation was decided upon. This I performed on Nov. 18th. The old scar was excised, and a complete removal of the enlarged glands on the left side of the neck was carried out. They were very adherent to the sterno-mastoid (which had to be divided) and also to the carotid sheath. A mass of glands extending from the clavicle to the angle of the jaw was removed. The wound was closed with a continuous suture and a drain inserted through a separate puncture hole in the skin flap. All went well until 1 A.M. the following day. The child had seemed very well considering the severity of the operation. His pulse, however, suddenly rose to 160 and became full and bounding. His temperature rose from 98° to 102° F., and the face became flushed and blue. The patient was now unconscious. There was no hæmorrhage from the wound, which was opened up and washed out. Saline was administered and stimulants and heat supplied, but he died two hours later—12 hours after operation. He vomited only once, shortly before death. The urine was free from acetone or diacetic acid.

CASE 2.—The patient was a female aged 3 years and 8 months. There was a family history of pulmonary phthisis on the father's side. A lump appeared on the right side of the neck 18 months previously when the child was in South America. This swelling was allowed to burst; it discharged pus for some time after. There had been a small sinus over the gland ever since with a slight discharge which during the last three weeks had been worse. On admission the patient was found to have a typical tuberculous sinus leading down to a deep gland, with which was associated considerable peri-adenitis. On Jan. 16th, 1913, I performed a radical operation for removal of the glands on he right side of the neck. A long incision was carried long the anterior border of the sterno-mastoid in the usual manner, commencing below and behind the mastoid above nd ending immediately above the clavicle. The incision ncircled the sinus in such a manner that this was removed *n bloc* with the glands. Care was taken to remove the chain f small glands along the outer aspect of the jugular vein. The wound was closed and a drain inserted as in Case 1. The child seemed very well on the evening of the operation, but about 4 o'clock the next morning she woke up with a cream and had a rigor. Her pulse was found to be 160 and her temperature 106° F. She was unconscious and lay muttering to herself. She was a little restless at first, with witchings of her limbs. She presented signs of an acute toxæmia with her high temperature, rapid bounding pulse, lushed rather cyanosed face, and unconsciousness. There was no acetone or diacetic acid in the urine, and no vomiting. She was kept warm by means of a 16-candle power lamp in the bed in the manner employed as a routine at the Victoria Hospital. Strychnine and digitalin were administered as the heart flagged, and finally an intravenous injection of sodium bicarbonate was given in deference to the opinion of one who believed the condition to be an acidosis. The patient died at 12 noon—20 hours after the operation.

The cause of death.—Unfortunately no post-mortem examination was permitted in either case, but in the second I obtained a specimen of the heart's blood by puncture soon after death. A swab was also taken from the wound, and these two were sent to the Lister Institute for bacteriological examination. They reported the presence in the blood and on the swab of "a short-chained streptococcus, presumably the same family in both instances." There can be little doubt that the cause of death in this second case was a hyperacute invasion by streptococci, and I am equally convinced, from the similarity of the clinical pictures, that this was the cause of death in the first case also. There were none of the classical signs—vomiting, extreme restlessness, and acetonuria—of a delayed chloroform poisoning, though this drug was used as the anæsthetic in both cases. The suddenness of the onset rather favoured embolism, and in the absence of a post-mortem examination this cannot be absolutely negatived. However, the pyrexia, the full bounding pulse, and the flushed, rather cyanosed, face were indicative of a severe blood infection rather than a massive infarct. Further, the wounds were thoroughly opened up during life, and there was seen to be no sign of thrombosis in the jugular vein.

Origin of the infection.—It is extremely improbable that the streptococcus was extraneously carried into the wound through imperfect operative technique. I think that this source can be ruled out at the outset. It is almost certain, however, that the operation lighted up a smouldering infection. In this connexion it will be remembered that sinuses were present in both these cases. In the first case this followed aseptic incision and curettage and had been antiseptically treated in the wards till the time of the second operation. Nevertheless there had been an inflammation in the gland, non-pyogenic, and therefore very likely a mild or thwarted streptococcus infection. The sinus in Case 2 had been present for some 18 months, and had had household treatment only for some time previously. It is highly probable that organisms were already lurking in the sinus, and probably in the gland tissue and lymphatics also. The manipulation necessary for the removal of the glands would very likely cause a spilling of infective material into what is really a very large open wound. Absorption would very readily take place directly into the blood or *viâ* the deep lymphatics and thoracic duct (Thiele[1]).

Dr. A. Stanley Griffith, of the Field Laboratories, Cambridge, to whom the glands of Case 2 were submitted as material for his research upon the varieties of tubercle bacilli found in cervical glands, did not find any streptococci in the glands themselves. But as he said in a letter: "I am afraid my investigation, confined as it is to the purely tuberculous tissue, will not be of much help to you in deciding whether the streptococcus infection started before or after the operation." However, his examination of the glands from this case is so interesting that I cannot do better than quote his notes at length.

> The material consisted of a group of glands and several separate ones. The group was attached to a diamond-shaped piece of skin, in the centre of which was a sinus. The latter was found to end in dense fibrous tissue which was apparently the remains of a tuberculous gland, the contents of which had been evacuated. Below this fibrous patch were two enlarged glands which contained dry caseo-calcareous masses which readily shelled out from a fibrous capsule; a third small gland contained a caseo-calcareous tubercle. The other (separate) glands appeared slightly enlarged, but were not obviously tuberculous. An emulsion was made of the caseo-calcareous substance and inoculated into guinea-pigs. Cultures were also sown with the caseo-calcareous substance, but these have so far remained sterile; no streptococci have grown. I found no organisms of any sort in a smear preparation of the emulsion. ...... Two guinea-pigs were inoculated with an emulsion from two glands and neither of them developed tuberculosis. All the cultures sown with the emulsion remained sterile. There were therefore no streptococci or living tubercle bacilli in the material investigated.

Hence we see that the caseous material at least was found sterile. Whether the sinus would have been found sterile or not is another matter. And the same is true of the organised material removed—the capsules of the glands, the fibrous tissue, and lymphatics. In these cases with sinuses there is probably a fairly rich bacterial flora in the sinus walls and in the numberless lymphatics which are necessarily cut across at operation.

Other cases.—In looking through the records of the Victoria Hospital, Chelsea, for the past 25 years I found but four deaths in 533 operations on tuberculous glands, a mortality of 0·75 per cent. The four deaths were these:—

1. Died eight days after from tuberculous meningitis.
2. Tuberculous abscess with sinus; curettage; death from erysipelas.
3. The notes state that after liberating pus "breaking-down gland tissue extending in all directions ...... was with difficulty and violence scraped away, a large ragged cavity finally remaining." The child died the following evening with a temperature of 107·8° F.
4. At operation hæmorrhage was severe; wound opened and packed after four dressings. Frequent coffee-ground vomiting; pain in abdomen. Diacetic acid in the urine. Temperature rose to 105·2°. Child died just over 24 hours after operation (typical delayed chloroform poisoning; excluded in my cases).

These four cases represent practically the only four possibilities of death following operation on cervical glands. Presumably Cases 2 and 3 are both deaths from acute streptococcal infection, but of a grosser and more obvious nature than the two cases I have reported above. The medical profession has been wont to regard the operation of removal of tuberculous cervical glands as safe if tedious.

Prophylaxis.—The lesson to be learned from the above rather bitter experiences is that careful attention must be paid to sinuses for a few days before operation. They should be well swabbed out daily with iodine or carbolic alcohol. It would be well in most cases to obtain a culture from the sinus before determining the date of operation. As for treatment, once the bacteriæmia has set in probably no remedial measures will be of avail. The wounds were opened and flushed out with saline in both cases without success. In these hyperacute infections little can be expected from anything but intravenous anti-serum, and little enough from that. The body weight of these victims is so small that a comparatively small dose of streptococci will be lethal.

---

[1] F. H. Thiele: Channels of Spread of Bacterial Infection, Royal Society of Medicine, 1913 (Thiele and Embleton).

Finally, a note on the operation itself. It is now customary to remove all the glands of the affected side of the neck in a manner only slightly less thorough than if they were malignant. There can be no doubt but that this is the ideal method of treatment (Müller[2]), as by this means not only the obviously affected glands but also those which are in the incipient stage are thoroughly removed. Close attention should be paid to the small glands on the outer side of the carotid sheath, as these are very liable to become affected and spread the trouble into the posterior triangle. Indeed, Judd[3] plans his incision entirely in the posterior triangle so as to remove the "Fettpolster" of Merkel, and goes on to strip the deep cervical chain from behind.

Summary and conclusion.—1. The radical removal of tuberculous glands in the neck, whilst the only rational procedure, is not unfraught with danger. 2. This is especially the case in the presence of a sinus. 3. Two cases operated upon by me died from a fulminating streptococcal infection, one 12 hours, the other 20 hours after operation. 4. The exact source of infection was not discovered, but was probably the walls of the sinuses present. 5. Prophylactic treatment should be carried out for a few days before operation—the sinuses should be well swabbed out with iodine or similar antiseptic. 6. The wound should be well washed out with saline before it is closed and drainage employed, preferably through a separate stab wound in the skin flap. 7. In children at least probably no treatment will avail when once the bacteriæmia is established.

I desire to express my indebtedness to Mr. Joseph Cunning, whose house surgeon at Tite-street I was, and who very kindly allowed me to operate upon and report these two cases. I am also indebted to Dr. Griffith for the excellent report he so courteously furnished me with.

Victoria, British Columbia.

CAMBRIDGE RESEARCH HOSPITAL.—The studies which are being carried on at the Cambridge Research Hospital in connexion with rheumatoid arthritis and allied diseases have reached a stage at which it is essential that those working at the hospital should be provided with a properly equipped operating theatre, in order that more advanced research may be undertaken into the cause and treatment of these diseases. As there is no room suitable in the present building it will be necessary to build, and Mr. Otto Beit has generously promised the sum of £700 for the erection of this building, and has further promised the sum of £100 per annum for the next ten years towards the general maintenance of the hospital.

CONGENITAL ICTERUS.[1]

By SPENCER SHEILL, F.R.C.P. IREL.,
LATE EXAMINER IN MIDWIFERY AND GYNÆCOLOGY TO THE CONJOINT BOARD OF IRELAND; EX-ASSISTANT MASTER, COOMBE MATERNITY HOSPITAL, ETC.

IN his "Lectures on Diseases of Children" Dr. R. Hutchison aptly states that "so soon as the child is born it meets with various adverse influences which may render it the subject of disease before it has hardly begun to live." Had he said, "So soon as the seed is sown, or earlier than this, adverse influences are frequently active in harm for the future generation," he would have been equally correct and his words would have carried a greater significance. In the subject under consideration—congenital icterus—post-natal influences are of small moment, for the factors which are working to produce the abnormalities observed in such cases exert their principal energy during intra-uterine life, and they may even be hereditary.

Let me first very briefly compare the various forms of icterus neonatorum so that there will be no misconception as to the particular form to which I wish to draw the attention of the section. The simple jaundice so often met with occurring during the first week of life is really better called pseudo-jaundice. It is generally believed by the best observers to be due to inability of the liver to discharge sufficiently rapidly *viâ* the bile the products of red-cell disintegration. This red-cell destruction is, as you are aware, a normal process in the new-born, the child born with 5½ or 6 million red corpuscles per c.mm. and 110 per cent. of hæmoglobin having normally at about the end of the second week but the usual 5 million cells of the adult. It is believed that the débris so created renders the bile unduly viscid; that the bile capillaries become over-filled, and reabsorption follows stagnation of bile with consequent jaundice. In this form the conjunctiva is not injected, and the stools are not clay coloured. The trouble is transient and always benign. The blood origin of the affection has set some observers carefully comparing the effect upon the infant, as regards jaundice, of early and late ligature of the umbilical cord, with the result that a larger percentage of infants were found jaundiced when the cord was ligated late, thereby permitting more placental blood to reach the child.

The form of jaundice in which the conjunctiva is deeply injected, the stools colourless, the urine loaded with bile-pigment, and the child unduly drowsy, is said by some to be due to similar causes as the pseudo form, but in more marked degree; by others to be due to patency of the ductus venosus with lowered tension in the portal circulation and increased tension in the bile capillaries: but whatever its origin it seldom progresses to convulsions, coma, and death.

I need say little about the septic form of jaundice due to cord infection—its pathology is well known and its prevention simple. Syphilitic disease is usually recognisable by other signs and symptoms, and if liver degeneration is not too far advanced appropriate treatment is effective.

There remain, then, two forms of icterus—excluding Winckel's disease and Buhl's disease—to be discussed: namely, congenital abnormalities of the bile passages and familial jaundice. In the former there may be a defective development of the cystic or hepatic ducts early in intra-uterine life, creating a sluggish discharge of bile and followed by irritation of the ducts, then catarrh, and finally obliteration. The process is slow and may be completed during intra-uterine life, or not until a few weeks or months after birth. One can say with some certainty whether obliteration has occurred early or late by observing the meconium voided, which is normal if the obstruction has taken place late in intra-uterine life or after birth.

---

[1] A paper read before the Obstetrical Section of the Royal Academy of Medicine in Ireland on April 3rd, 1914.

The treatment of this form of jaundice is, of course, early operation, but there is always the difficulty of recognising the obstruction sufficiently early to ensure a good result, for the signs and symptoms are so similar to those of simple or pseudo-jaundice that the affection may have progressed beyond the possibility of recovery ere the obstruction be suspected, and one cannot always palpate with certainty a dilated gall-bladder. Moreover, the obstruction is not always amenable to operation as the process may have spread deeply through the liver itself. The family history of these cases helps us but little, and it is the same with the familial or hereditary form of jaundice—a rare form, the pathology of which is far from being clearly understood.

In looking through the scanty literature on the subject one finds the following points standing prominent: 1. The parents are usually healthy, and syphilis is not an important factor. 2. A tendency for several children of the same family to be similarly affected. 3. Other children of a family in which a fatal case of jaundice has occurred have been affected with infantile jaundice, or were unduly subject to digestive disturbances. 4. Boys were more frequently affected than girls.

In familial jaundice there is a tendency to spontaneous hæmorrhages from the umbilicus, bowels, or nose. The hæmorrhages are alleged to be due to the effect upon the blood-vessels of ptomaines circulating in the blood in quantity, following upon derangement of liver function, but they may be due also to an anæmic condition sometimes found in these cases. But whatever be their cause they are of ill omen, the little patient usually dying in coma or convulsions. Treatment would appear to be useless, and seeing our ignorance of the pathology this is not to be wondered at. A case of this nature recently came under my care, and the following brief sketch of it may be of interest.

The mother was hardly what one would call perfectly healthy, for she suffered from time to time from what she called "liver attacks." Appendicitis, gall-stones, and liver chills were prominent amongst the names of her ailments as diagnosed by various medical men. There can be no doubt, however, that she suffered from aggravated constipation for years, and as cause or effect her colon was chronically much dilated. She came to me first, when pregnant about five months, with a history of losing two infants shortly after birth from jaundice. Questioning her husband or herself elicited no information of any value. She had several "liver attacks" during this pregnancy, and she was very "nervy" at times, and prone to faintness when in a warm atmosphere, such as the kitchen. Her heart was sound, and the urine contained no abnormality at any time while under observation. Epigastric pain was a fairly frequent and annoying symptom.

After an easy normal labour, at the end of which a little chloroform was administered, I delivered her of an apparently perfectly normal male child. The infant showed a faint icteric tinge in the skin at birth, and this became rapidly deeper and deeper to the end. The child was very cross and fretful, and cried feebly most of the time. After 48 hours, as the little patient appeared to be going the way of its predecessors, I asked for a consultation with a surgeon, as a result of which he operated on the infant immediately in order to relieve what was diagnosed as obstruction to the outlet of bile. On opening the abdomen the gall-bladder was found moderately distended with very viscid bile. The ducts were patent, but the lumen could hardly admit of the passage of so thick a fluid as the bile found in the gall-bladder. The gall-bladder was drained, but the infant died about nine hours later. No post-mortem examination was permitted, but the weight of evidence indicated that we were dealing with a case of "familial jaundice," that the disease was antenatal, and that the abnormality lay in the bile itself rather than in the bile passages.

Naturally, in view of these facts, one is bound to ask, What is the cause of this unduly viscid bile? And if that question is answered by saying, what I believe to be the case, that it is due to a hereditary tendency to hæmolysis more precocious and more marked than is normal, then we must go further and seek a cause for the advanced hæmolysis. Some of these cases show a profound anæmia with a large percentage of megaloblasts. My case was anæmic, but not to a marked degree.

In spite of the fact that John Thomson, Summons, and others have found the parents mostly healthy in these cases, I feel unwilling to dissociate the fact of the mother's tendency to "liver attacks" in my case from the fatal icterus of the infants. One such case can prove nothing, but other observers have suggested that "familial icterus" is due to a poison circulating in the maternal blood, and the point is undoubtedly well worth investigating.

My special regret regarding this case is the incompleteness of my observations upon it and the inability to examine the cadaver. May I suggest that in the blood, and in the organs associated with the making and purifying of the blood, of both mother and infant much hidden information may lurk, and that we should in all suspicious cases thoroughly, *and above all early*, make a complete microscopic investigation of the blood.

Dublin.

THE RÔLE OF THE CRUCIAL LIGAMENTS IN HÆMARTHRUS AND INJURIES TO THE KNEE.[1]

BY EDRED M. CORNER, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL AND THE CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.

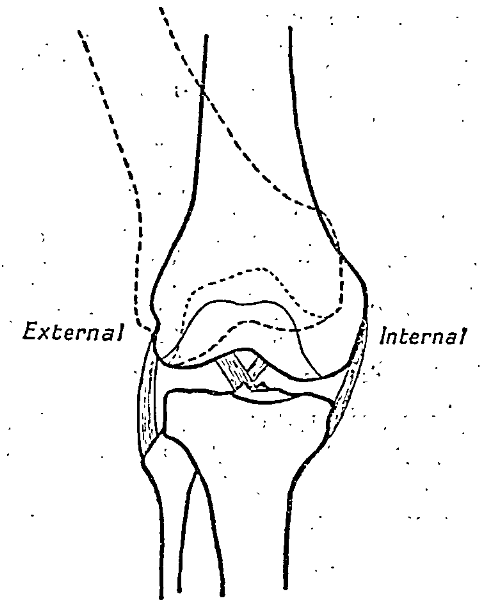
I PARTICULARLY wish to demonstrate the case of this young man. He injured his knee some four weeks ago whilst playing football, and has come to the hospital now for advice, as the injured knee is slow to get well. The pain, tenderness, and source of disability are placed without hesitation on the inner side of the knee. The rest of the knee is apparently normal and without pain. Thus at a glance the diagnosis is clear: partial rupture of the internal lateral ligament of the knee—partial only and not complete, as the knee does not allow of the leg being abducted at that joint. At the site of the lesion the outlines of the internal condyle of the femur and the tuberosity of the tibia are obscured by a tender swelling—extravasated blood around the ruptured fibres of the ligament. On asking the patient if the knee swelled up after the injury, he answered "Yes," but to no great extent and within a short time of the accident, an hour or two.

---

[1] Portions of an address to the Surbiton and Croydon Branches of the British Medical Association.

s the swelling of the joint took place so oon after the accident there can be no doubt iat the fluid within the swollen joint was in rge part blood. Where can this blood have ome from?

The internal lateral ligament was only partially orn, and the synovial membrane of the joint is osely attached there. Hence the synovial membrane would not have been torn with the ligament. as the synovial membrane torn by the movement the internal semilunar cartilage? The extreme calisation of the pain to the side of the joint says No" to this. Had any movement of the cartilage arked enough to tear the synovial membrane ken place, pain would have been felt more teriorly, to the front and side of the joint, and e swelling of the joint after the accident would ve been greater. Where, then, did the blood me from? And why was so easily torn a structre as the internal lateral ligament only partially ptured? The true reason is that the tearing of e lateral ligament was stopped as the strain gan to be taken up by the strong crucial ligaents inside the joint. These latter ligaments thstood the strain, and the internal lateral gament was only partially and not completely ptured. (See figure.) Indeed, complete rupture the internal lateral ligament of the knee is possible without a complete rupture of the cial ligaments, or at least a complete rupture of e anterior crucial ligament.



The illustration shows the knee-joint, its two lateral ligaments, and the crucial ligaments. The dotted outline represents the femur when the joint is bent inward, and serves to show how the crucial ligaments take up the strain as the fibres of the internal lateral ligament yield.

Hence in lateral strains, sprains, or stresses of e knee it can be formulated:—1. Partial rupture the internal lateral ligament is produced by the cial ligaments withstanding the strain of the cident and preventing complete rupture. The ults of treatment will be satisfactory. 2. Comte or severe lacerations of the internal lateral ament will always be accompanied by a lesion of e crucial ligaments, even to the complete rupture the anterior crucial ligament. The results of atment vary *pari passu* with the extent of the laceration of the crucial ligaments. The convalescence may be long and the final result unsatisfactory.

I have spent so much time upon the injury to the crucial ligaments to demonstrate and insist on their almost universal presence in cases of injury to the knee. So that a further statement may be made. The synovial membrane of the knee is tightly bound down to these crucial ligaments, so that when the ligaments bear strain and are stretched the synovial membrane on them is torn, not in one place, but as many small tears. These tears are the main source of blood in the joint after an injury—cases of hæmarthrus. Hence it is found with regard to the patient under consideration—where the crucial ligaments withstood the strain and were not broken, and where the synovial membrane would be but little torn—there was but little early swelling of the joint after the accident. Little blood was poured into the joint as the synovial membrane was little torn. How different this clinical picture is from that of the man who, as was proved by operation, ruptured his anterior crucial ligament. That man's joint swelled up enormously and quickly after the accident. Also the tenderness on the inner side of his knee extended so far forward that a lesion of his internal semilunar cartilage was suspected, the unoffending cartilage being removed at Malta. He is an example of the extremely unsatisfactory result of treating the ruptured internal lateral ligament and excluding all treatment for the coexisting injury to the crucial ligaments—a fact noted by Mr. A. M. Martin, of Newcastle-on-Tyne.[2]

Such reasoning as the above explains the relationship to each other and to injuries of the knee of partial rupture of the internal lateral ligament, complete rupture of the same ligament, partial or complete rupture of the crucial ligaments, and the source of blood in the knee-joint after injury (hæmarthrus). These have many consequences, but the one at present worthy of notice is that very little reference has been made in these clinical observations of injuries to semilunar cartilages. These cartilages move and bear stress in all movements of the joint. But operation, and probably removal of the semilunar cartilage, is not a "cure-all" for troublesome conditions found in knees which have sustained injuries. The popularity of this operation suggests that such may be the opinion, and that this operation is done with as small amount of forethought as is so often given to the operations for the removal of an appendix, varicocele, or hernia sac. The post-operative benefit in these cases is often due to some post-operative stiffness giving the joint an appearance and feeling of strength.

Clinically there is a lesson to be learned. If the early post-traumatic swelling of a joint is slight and symmetrical, there is little intra-articular injury and the patient will do well. If the early post-traumatic swelling of the joint is rapid and great, there is an important intra-articular injury (or injuries) to be found in the neighbourhood of the crucial ligaments. The convalescence of such a case will be long, and the end results of any treatment short of operative treatment unsatisfactory.

It may be asked how such an operation should be done. The answer is, through a median arthrotomy, splitting the patella longitudinally, the knee being flexed to expose the structures at the back of the joint. There is no need to wire the patella after this operation; the split rectus femoris and ligamentum patellæ are sutured.

---

[2] Brit. Med. Jour., Oct. 25th, 1913.

And what is the time to operate? As soon as the post-traumatic bleeding has ceased and before any post-traumatic inflammation has begun—that is to say, if circumstances allow, operate a few hours after the injury. Professor Murphy, of Chicago, likes to wait a few days after the injury. During this period he injects some formalin solution into the joint which "coffer-dams" the subsynovial lymphatics and so prevents any infection spreading from the joint.

Harley-street, W.

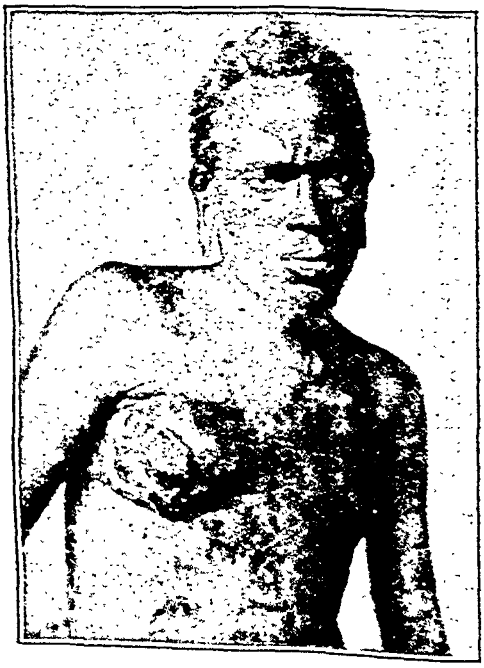
A CASE OF CARCINOMA OF THE BREAST IN A MALE.

By H. V. WELCH, M.B., B.S. LOND.,
MEDICAL OFFICER, BRITISH EAST AFRICA.

THE appended reproductions of photographs of a case of carcinoma of the breast in a male may prove of interest to readers of THE LANCET.

The patient, a Kikuyu, aged 42, first came up to the native hospital at Nairobi, complaining of the pain caused by the growth. The surface of the tumour was very foul and ulcerated. (Fig. 1.) The axillary and supraclavicular glands were hard and enlarged. The patient dated the history back only two months, but I imagine that that was when pain was first troublesome.

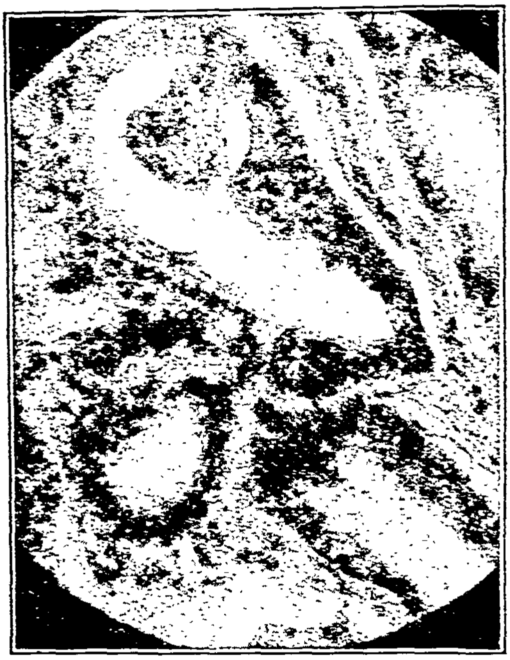
FIG. 1.



Reproduction of photograph of patient showing growth before removal.

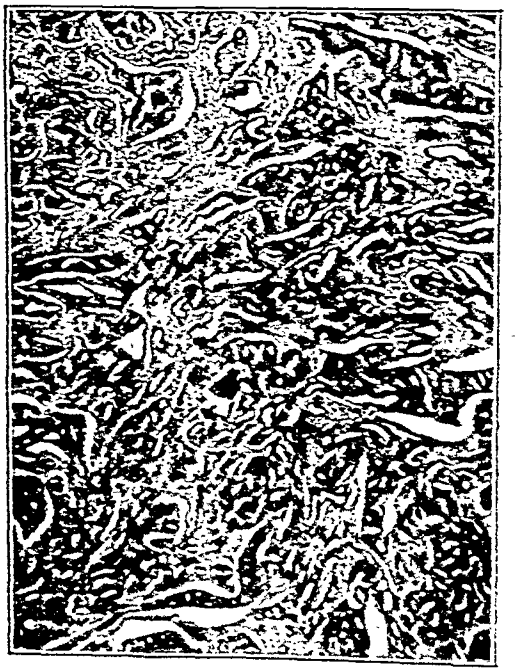
Operation was recommended to ease the pain rather than in hope of cure. Owing to the extent of the growth it was only possible to remove the tumour as widely as possible, and not attempt to clear the axilla. On section the growth showed the typical appearance of adeno-carcinoma. (Figs. 2 and 3.)

FIG. 2.



Microscopical appearance of growth under low power.

FIG. 3.



Microscopical appearance, high power.

Quite apart from the infrequency of breast cancer in a male, malignant disease amongst the natives in this country is extraordinarily rare.

I am indebted to Dr. J. H. H. Pirie for the sections, and to Mr. Crichton for the photographs.

A NOTE ON THE ASPIRATORY FUNCTION OF THE HEART.

BY H. WALTER VERDON, F.R.C.S. ENG.

THE heart is a pump and, like the mechanical pump, possesses aspiratory and propulsive powers—aspiratory power to draw supplies from pulmonary and systemic veins, and propulsive power to discharge the contents of its ventricles into pulmonary and systemic arteries. The heart works in a minus-pressure environment which at the height of inspiration registers 30 to 50 mm. Hg and during expiration falls to half this measure. Since fluids flow in the direction of the least resistance a centripetal current of blood from pulmonary and systemic sources sets in towards the minus-pressure environment of the heart, filling the great tributary veins, the auricles, and the ventricles. Intrathoracic minus pressure thus constitutes a potential aspiratory force which keeps the central venous system perpetually full of blood, and maintains this section of the circulation under favourable conditions for the action of the kinetic aspiratory function of the ventricles.

The kinetic aspiratory function is intermittent and exercises itself only during systole. When the cone of the heart contracts and expels the contents of the ventricles into pulmonary and systemic arteries it vacates a section of the pericardial sac, a space which is instantly filled by the head of the venous column entering and expanding the auricles—the advance movement being rendered imperative by the *vis a tergo* of atmospheric pressure exercised upon the contents of pulmonary and systemic veins lying at the foot of the venous column. The impetus of the moving column of venous blood transmitted to the cone of the heart is felt upon the thoracic wall; hence the quality of the apex beat affords a fair indication of the efficiency of the aspiratory function, a term which denotes and includes both the potential and the kinetic forces of aspiration.

The aspiratory function may be lowered by asthenic states of the myocardium or by reduction of the minus pressure of the environment. The latter event occurs when the fibrous stroma of the lungs loses its elasticity, when the musculature of the diaphragm and the thoracic wall becomes atonic, when intrapleural and intrapericardial effusions accumulate, and when pressure from the abdomen reduces the capacity of the thoracic cavity.

When aspiratory function is lowered certain phenomena occur. *Vis a tergo* of atmospheric pressure loses its potency, and intrathoracic venous circulation languishes. Diastole of the right ventricle and that of the auricles is sluggish, and the current in pulmonary capillary circulation is slow. Congestion of the pulmonary stream and stasis in bronchiolar radicles display themselves in symptomatic expression by asthma and dyspnœa. High peripheral resistance in the pulmonary field leads to high tension in the right ventricle, which, unable to discharge its contents fully, becomes the receptacle of a residual accumulation of blood. The barrel chest of emphysema is the result of attempts made by inspiratory musculature to neutralise the untoward effects of minus-pressure insufficiency.

Contrast circulatory conditions prevailing in states of low intrathoracic minus pressure, as in emphysema, with those obtaining in the incipient stages of fibroid phthisis, when minus pressure is high, owing to contraction occurring in the fibrous stroma of the lungs. In the latter instance the heart is small. Asthma and pulmonary congestion are almost unknown, and the freshness of the complexion as compared with the greyness of the skin of the emphysemic is a matter of note. The falling in of the chest wall at later stages points to the existence of excessive degrees of minus pressure. This condition is also apparent in the well-defined deflexions of the jugular curve, which contrasts sharply with the featureless appearances of the jugular curve of the emphysemic.

In the recumbent posture, when the shoulders are depressed, the diaphragm seeks a high horizontal plane of activity; intrathoracic minus pressure is correspondingly reduced and aspiratory function is lowered. Hence this posture is intolerable to the subject possessed of a weak aspiratory function. When the trunk is upright the liver, attached by its suspensory ligament to the aponeurosis of the diaphragm, seeks a lower situation in the abdominal cavity, drawing down with it the diaphragm, which now engages itself upon a deeper plane of action. For this reason the subject of a weak aspiratory function even during the hours of sleep assumes an upright pose. When the aspiratory function is excessively low the patient stands up, resting and fixing his arms and bent shoulders over some object of support. He thus secures a depending liver, and at the same time obtains a *point d'appui* from which inspiratory muscles attached to the thoracic wall may exercise themselves with effect. By this means the fullest measure of intrathoracic minus pressure is secured.

To speak of the limitation of the movements of the heart through the direct effects of abdominal pressure is incorrect. The heart is suspended in a bony cage, and the arching of the diaphragm is limited by unyielding aponeurotic structures. Thus when the diaphragm has attained its highest plane of elevation ample room remains for the heart to disport itself without let or hindrance. Nevertheless the heart is affected by intragastric and intra-abdominal hyper-pressure—the one condition determining sympathetic acceleration or vagal inhibition, the other inefficiency of the aspiratory function.

The object of this paper is to draw the attention of the practitioner of medicine to a subject of clinical importance, and one having a bearing upon treatment—a subject which has suffered strange neglect at the hands of the cardiologist. Upon turning over the pages of several recent works upon heart disease I have not found so far even bare mention of the subject.

Streatham hill, S.W.

LECTURES ON MEDICAL HYDROLOGY.—A course of lectures on Medical Hydrology (Hydrotherapy and Medicinal Springs) will be delivered at the Post-Graduate Medical College and Polyclinic, Chenies-street, London, W.C., on May 11th, 12th, 13th, and 14th, at 5.15 P.M., by Dr. R. Fortescue Fox. The lectures will deal with the effects of heat and cold, the principles of hydrotherapy and its application to acute and chronic disease; the rationale of bathing procedures—cooling, sedative, thermal, and hyperthermal—employed both at home and at medical baths; medicinal springs and baths, and the choice of health resorts; and indications for hydrological treatment. All medical practitioners interested in hydrology are invited to attend

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

Observations on CO_2 in Alveolar Air of Diabetics.—Aplastic Anæmia.—Multiple Superficial Ulceration of the Stomach.—A Pedunculated Intrabronchial Tumour (Sarcoma) causing Bronchiectasis.

A MEETING of this section was held on April 28th, Dr. SAMUEL WEST, the President, being in the chair.

Dr. E. P. POULTON read a paper on Observations on CO_2 in the Alveolar Air of Diabetics, especially in relation to the onset of Coma, and demonstrated Fridericia's method of measuring it clinically. He said that Beddard, Pembrey, and Spriggs were the first to draw attention to the fact that the partial pressure of CO_2 in the alveolar air of diabetics fell with increasing acidosis to reach a very low point in coma. When low the alveolar CO_2 could be raised by the administration of sodium bicarbonate. Straub and Fridericia had both confirmed their results. In the present communication stress was laid on the importance of measuring the alveolar CO_2 as a guide to treatment and prognosis in diabetes. The advantage of using this method was that the results gave a measure of the actual acidosis—i.e., of the amount of β-oxybutyric and diacetic acids present in the arterial blood at the moment. A clinical apparatus devised by Fridericia had been used for these determinations, and gave satisfactory results for clinical purposes. The method only took about ten minutes to accomplish. The normal values in healthy individuals for the alveolar CO_2 usually lay between 5 and 6 per cent. The same values were obtained in mild diabetes, where the acidosis was at a minimum. However, values down to 4 per cent. indicated that the patient was perfectly secure against the onset of coma for the time being. Values between 3 and 4 per cent. indicated the presence of danger, and it was important to take measures to raise the value if possible above 4 per cent. In none of the cases examined had coma supervened in less than two days after a reading of between 3 and 4 per cent. had been obtained. There was thus plenty of warning. Values of from 2 to 2·5 per cent. indicated the rapid onset of coma, probably within 24 hours, unless immediate improvement occurred. The values obtained actually during coma varied from 0·8 to 1·5 per cent. These values could, of course, only be measured by special methods—i.e., Pembrey's or Hasselbalch's modifications of the Haldane-Priestley method. The clinical method was inapplicable. Detailed charts of the values of nine cases of diabetic coma were shown and of six milder cases of diabetes.

Dr. F. PARKES WEBER read a paper on a case of Acute Aplastic Anæmia, with a Note on the Nomenclature of Plastic and Aplastic Anæmias. He said that the chief points of the case might be summed up as follows. A young man, who had previously enjoyed apparently fair health, though he had (as the necropsy showed) formerly had a slight tuberculous affection of the apices of the lungs, suddenly contracted some kind of microbic infection of the mouth, showing itself by gingival stomatitis, a phlegmonous induration of the right cheek, and considerable pyrexia. From all this he completely recovered, but with the onset of the mouth disease there was associated a grave form of anæmia, which proved rapidly progressive, and in spite of the improvement in his mouth condition ended fatally in ten weeks from the apparent onset. This anæmia differed from typical so-called "pernicious anæmia" and from grave secondary anæmias in its being much more pernicious and much more rapidly fatal. Blood examinations showed the almost complete absence of any "megaloblastic reaction" and of the blood-regenerative changes, generally so much dreaded as a characteristic sign of the presence of pernicious or of grave secondary anæmias. In the present case poikilocytosis, anisocytosis, and polychromatophilia were absent or only slightly marked, even when the total number of erythrocytes fell to below 1,000,000 in the cubic millimetre of blood. There was never decided megalocytosis, and still less was there any megaloblastic reaction such as is characteristic in pernicious anæmia; in fact, there were few megalocytes, and nucleated red cells (erythroblasts) were almost completely absent. The colour index of the red cells varied greatly (from about ½ to 1), but it was usually much lower than 1 instead of being higher than 1, as it would probably often be in characteristic cases of pernicious anæmia. Simultaneously with the fall in the red cells there was likewise a great reduction in the number of the white cells (leucopenia), which were only about 2000 instead of the normal 5000–8000 in the cubic millimetre of blood. Of the white cells the lymphocytes were least affected, and all the differential counts of white cells showed a decided relative lymphocytosis; but this was only relative, for the total lymphocytes numbered only 814–1550 in the cubic millimetre of blood, instead of the normal average—namely, about 1400–2000. The white cells particularly reduced in number were those derived from the bone-marrow, notably the polymorphonuclear neutrophiles, which at one count numbered about 1000, instead of the normal 4000–6000, in the cubic millimetre of blood. The quantity of blood platelets was decidedly diminished below the normal standard. The clot which forms in the watery blood from cases like the present one was said by French observers not to retract normally, but this was not tested in the present case. The main features of the disease were accounted for as those of an anæmia due to blood destruction, almost entirely unaccompanied by conservative blood-regenerative changes on the part of the hæmopoietic tissue of the bone-marrow. The condition might therefore justly be termed, as it was termed, "acute aplastic anæmia." Genuine examples of acute aplastic anæmia were probably invariably rapidly fatal like the present one, but conditions of chronic aplastic anæmia, characterised by a variable chronic anæmia with deficient signs of blood regeneration, likewise existed, which belonged to a different category. One suggestion was that cases of acute aplastic anæmia were due to the initial infection being of a peculiar nature, the resulting toxins in the blood having the power more or less completely to paralyse or destroy the hæmopoietic functions of the bone-marrow. But the initial infection need apparently not always be a severe one, and it could obviously be argued that the severity and peculiar fatal character of acute aplastic anæmia were due to some preceding, though possibly hitherto latent, peculiarity of the affected person—a peculiarity manifesting itself by the inability of his hæmopoietic bone-marrow to react efficiently in response to even moderately urgent demands on it. Be that as it might, whether the condition was due to some exceedingly virulent septic infection or to some unknown and rare infection (which had the power of paralysing or destroying the hæmopoietic functions of the infected individual), or due to an idiosyncrasy or a temporary or chronic peculiarity (deficiency in hæmopoietic response) on the part of the affected individuals, the clinical features of a case of "acute aplastic anæmia" were sufficiently striking to give it a place by itself amongst the rarest diseases or symptom-complexes of the blood and blood-forming apparatus. This rapidly fatal kind of "aplastic anæmia" might well be termed "aplastikæmia."[1] On the other hand, the chronic form of aplastic anæmia to which he had already alluded might be called "hypoplastikæmia," since it was really a chronic hypoplastic anæmia, due to congenital or acquired inability of the hæmopoietic tissues (under normal or slightly pathological conditions) to maintain the normal standard of blood quality (blood equilibrium); in other words, the hæmopoietic tissues in such chronic cases gave a deficient regenerative response to normal and pathological stimuli. Other anæmic cases of various kinds showing the ordinary characteristics of blood regeneration (cases of "plastic" anæmia as opposed to "aplastic" or "hypoplastic anæmia") could, of course, be divided into groups which might by the same method of nomenclature be headed "orthoplastikæmia" and "metaplastikæmia." These conditions of "aplastikæmia," "hypoplastikæmia," &c., might furthermore be contrasted to a state of what might be termed temporary or permanent "hyperplastikæmia," including cases of erythræmia (polycythæmia rubra) and some cases of erythrocytosis (secondary polycythæmia rubra), in which the hæmopoietic response of the bone-marrow to normal and pathological stimuli was excessive.

Dr. WEBER also described a case of Multiple Acute Ulceration of the Stomach. The patient, aged 47 years, was admitted to the German Hospital in February, 1914, in a very feeble, cyanosed, and dyspnœic state, not unconscious, but with her sensorium somewhat dulled. The history was that for 20 years she had been subject to winter cough and bronchitis, and that she had been more or less constantly ailing for the past two years. In June, 1913, she had been knocked down in the road by a cyclist. The present illness was said to have commenced with bronchitic symptoms about two weeks before admission. No special gastric symptoms had been noted, and there was no history of hæmatemesis, epistaxis, hæmoptysis, or melæna. In the hospital sharp crepitations were heard over the upper front part of the right lung. The other organs of the thorax and abdomen showed nothing remarkable. There was some œdema of the feet. The urine was scanty and contained a trace of albumin; no sugar. The respirations varied between 44 and 60 per minute, and the pulse between 112 and 130. The body temperature was never above 99° F. and never below 97°. In spite of treatment (oxygen inhalation, digalen, diuretin, ipecacuanha, subcutaneous injection of camphor oil) the patient died about 42 hours after admission. At the necropsy the upper part of the right lung was found to be in a condition of "tense œdema." There was some fresh pleuritic adhesion on the right side, with about 300 c.c. of clear serous pleuritic effusion. Microscopical sections of the affected part of the lung showed catarrhal and extreme emphysematous changes, and the presence of coagulated œdema fluid in the pulmonary vesicles made the sections appear under the microscope as if they had been cut in celloidin. No Gram-positive organisms were found. The right side of the heart was somewhat engorged. The spleen was of average size, and of hard rather than soft consistence. In the liver there was a transverse groove across the lower part of the front, such as is caused by "tight-lacing," and microscopically there was evidence of chronic passive congestion. In the remaining organs nothing specially noteworthy was observed excepting in the stomach. There was no ascites, and from the outer side (before it was opened) the stomach did not appear to be diseased. On opening it the mucous membrane was seen to be hyperæmic and thrown into longitudinal folds or "rugæ" by the contracted state of the muscular walls of the organ. There were no submucous or subserous hæmorrhages (nor was there any pus such as may be found in cases of "phlegmonous" gastritis). The unexpected feature was the presence of a great number of sharply cut ("punched-out") ulcers in the mucous membrane. At least 100 of these ulcers were counted, but there had probably been considerably more, as some of them appeared to have been formed by the coalescence of two or more smaller ones. They were distributed over all parts of the gastric mucosa, but were chiefly arranged in longitudinal lines on the projecting ridges or folds (rugæ). Some of them formed uneven slit-like depressions of considerable length on the convexity of these ridges. Some of the longer (linear) ulcers were possibly formed by the coalescence of smaller ones, but their slit-like appearance was, doubtless, in part due to the state of circular contraction of the muscular walls of the stomach. In the first part of the duodenum there was some hyperæmia but no ulceration. Microscopical examination of two of the ulcers in the stomach showed that they were superficial, the deepest part of the gastric mucosa remaining undestroyed and forming the ulcer floor. The mucous membrane, especially the ulcerated region, was moderately infiltrated with lymphocytes and polymorphonuclear cells, proving the ante-mortem nature of the change. The ulcers were, however, doubtless acute, as no signs of chronic inflammation were observable. No Gram positive organisms were found in the sections. There could be no doubt that the multiple acute superficial ulcers were in the present case of recent formation. They constituted, in fact, practically a "terminal" phenomenon, and probably both they and the local pulmonary œdema were due to the same infective agent (whatever the microbe in question might have been). Dr. Charles Bolton in his recent work on "Ulcer of the Stomach" had referred to two cases of multiple acute gastric ulceration of infective origin. In the stomach of one of these patients 431 ulcers, or lesions about to become ulcers, were found, whilst in the other patient's stomach there were about 250. Dr. Weber was indebted to his house physician, Dr. Sons, for much help in the examination of the present case, and to Mr. S. G. Shattock for kindly assisting in the microscopical examination.

---

[1] The spelling should of course really be "aplastichæmia," but it is the custom to write "leukæmia" instead of "leuchæmia."

Dr. J. A. BRAXTON HICKS described a case of Pedunculated Intrabronchial Tumour (Sarcoma) causing Bronchiectasis. His paper will be published in full in an early issue of THE LANCET.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Introductory Address.—Prognosis in Incipient Opacities of Lens.—Pigment in Iris of Child.—Flat Sarcoma of Choroid.—Microphthalmia.—Papillœdema in Disseminated Sclerosis.—Dressings and Antiseptic Methods in Ocular Operations.—Treatment of Dislocated Lens.—Post-operative Complications of Cataract Extractions.—Optic Neuritis and Spinal Myelitis.—Irido-sclerotomy in Glaucoma.—Diseases of the Eye in Animals.—Senile Cataract with Two Nuclei.—Death following Open Evisceration.—Exhibition of Cases, &c.

THE annual congress of the Ophthalmological Society was held at the rooms of the Royal Society of Medicine, Wimpole-street, on Thursday, Friday, and Saturday, April 23rd–25th, while a clinical meeting was held at the Central London Ophthalmic Hospital, Judd-street, W.C., on Friday afternoon. The chair was occupied by Mr. F. RICHARDSON CROSS, the President, and among the distinguished visitors were Professor Uhthoff, of Breslau, Professor Straub, of Amsterdam, and Professor Landolt, of Paris.

The PRESIDENT, in the course of a short introductory address, reminded members of the distinguished work of his predecessors in the chair—Bowman, Hutchinson, Hulke, Hughlings Jackson, Argyll Robertson, Berry, Sir Henry Swanzy, David Little, Priestley Smith, Nettleship, Tweedy, and Lawford—and expressed congratulation on behalf of the society to the Royal Society of Medicine on the success achieved by the Section of Ophthalmology. He referred to his investigations on the question of factory lighting, undertaken at the request of the Royal College of Surgeons of England, and thanked members for the help they had given him on the subject. Most of the replies, however, from members who practised in industrial localities showed that there were few ailments which could be attributed to the insufficient or bad lighting of factories; but the inquiry did not include such special work as glass making, or working on red hot or white hot conditions of metal, testing arc lamps, &c. Any injury done by excessive artificial lighting seemed to be attributable to the ultra-violet rays, as in the case of snow blindness; but the wearing of any glasses largely protected the eyes from the ultra-violet rays. The negative results of this inquiry did not lessen the necessity for aiming at a perfect form of lighting, which was an economic question, concerning not only the best results of work, but the hygiene of vision. There still remained much to be learnt as to the causation and treatment of eye diseases. All kinds of abnormal conditions of blood and system generally might set up inflammation of the intraocular blood-vessels, such as iritis, uveitis, episcleritis, retinitis, &c. He referred to the suggestion of Mr. Basil Hughes that instead of rheumatic iritis the term "metastatic iritis" should be used. It was very necessary to determine the etiological cause of the condition seen, for then measures could be taken to increase the patient's resistance to the particular organism, and of course any focus of disease must be energetically treated. He proceeded to speak of the selection shown by certain bacteria for particular localities, and said there was reason to believe that bacteria flourishing in their own particular locality might produce different strains showing a selection for other tissues. The view that there were evolutionary developments of bacteria seemed well justified. He also referred to the value of diphtheria antitoxin and the various hormones in ophthalmic work, as also the serum therapy which was so well initiated by Sir Almroth Wright. He spoke of the gonococcus being the most widespread cause of infectious diseases, and pointed out that the organism might remain latent in the body for years. He referred to the work of Carl Browning showing the close relationship between syphilis and interstitial keratitis, and primary optic atrophy, general paralysis of the insane, and locomotor ataxy, while half of the cases of iritis and one-fourth of the cases of choroiditis were shown to be syphilitic. The good effects of salvarsan and neo-salvarsan in eye disease, he said, were very marked. Dealing with the history of the Ophthalmological Society, the President reminded members that in 1880 a committee was appointed to consider defects of sight in relation to public safety, with authority to communicate thereupon with the Government on the part of the society if thought fit. In the following year an international committee, 14 nations being represented, was appointed "to deliberate concerning the tests of vision and colour sense most applicable to persons employed in working or observing signals by land or sea when the lives of others are involved." In the second volume of the society's Transactions appeared the resolutions arrived at, indicating how unsatisfactory the matter was at that time. If the advice tendered 30 years ago had been taken advantage of many disasters would have been prevented. The society also took an important step in 1884 in connexion with the prevention of blindness from ophthalmia neonatorum, and a special committee appointed brought forward certain resolutions, which were adopted. But the Local Government Board, Whitehall, declined to act on the suggestion that printed instructions as to the dangers should be handed to each person registering a birth, and despite several attempts it has not yet been possible to bring this about, notwithstanding the large number of cases of blindness due to this cause. But quite recently discretion was given to town councils and county councils to make the disease notifiable if they thought fit, and now ophthalmia in infants had become notifiable. It was, said the President, terrible to reflect on the number of people whose sight might have been saved if adequate measures had been taken so long ago.

Mr. W. H. H. Jessop read a paper entitled "The Prognosis in Incipient Opacities of the Lens."—Sir Anderson Critchett expressed his agreement with Mr. Jessop's remarks, and related the case of a clergyman, aged 48, who, when he consulted a young oculist, was told he had cataract, and so nervous was he in consequence that he insisted on presenting himself for examination every few months, fearing that he would be losing his sight. But his sight continued good, except for a slowly progressing presbyopia, until he was 86.—Professor Landolt agreed that cases such as those described by Mr. Jessop were often met with, and he thought the term "cataract" should be restricted to cases in which there was serious impairment of vision which finally required removal of the lens.—Mr. J. B. Story (Dublin) also expressed agreement, and suggested that the term "cataract" should not be used when, in the opinion of the observer, the condition was not progressive.—Mr. Leslie J. Paton described cases similar to those related by Mr. Jessop, and Dr. G. F. Alexander thought that the fine spicules often seen in the eyes of young people were congenital and had persisted throughout life.—Mr. S. Johnson Taylor (Norwich) also described such a case in which he was able to prevent a fruitless operation for a condition which was not progressive or detrimental to the sight.—Dr. George Mackay (Edinburgh), Mr. John Rowan (Glasgow), and Mr. C. Wray (Croydon) also discussed the paper, and Mr. Jessop replied.

Mr. N. Bishop Harman read a paper entitled "The Appearance of Pigment in the Iris of the Child." The observations were made on white children, the offspring of a blue-eyed, fair-haired father and a brown-eyed, dark-haired mother. At birth in each case the irides were of the usual dull slaty-blue colour, and the iris tissues were obscured as though coated in some smooth fine-textured material. Clearing of the iris stroma was noted from the third to the sixth week of life. Two children developed blue eyes, one blue with the suggestion of violet, due to rims of finer darker stroma at the margins. The other blue became bright and cold in tint owing to a marked thickening of the stroma in the intermediate zone. Two children developed brown irides. The first sign of brown pigment was noted at the sixth week. The pigment was in broad irregular patches extending from the basal margin; it looked just as though the iris had been touched with brown ink which was soaking through to the surface and towards the pupillary border. The development was earliest in the temporal half of the iris. The patches extended and fused until the whole was brown. The tint became full and pure in one child; in the other there remained at the age of 2 years some suggestion of bluish or greenish tint at the depth of the crypts of the iris. In none of these cases was there any of the fine scattered pigment that is so common a feature of the hazel and dirty blue irides, and which forms an irregular ring about the pupillary margin. From a few observations it was thought that this surface pigment spread from the pupillary margin at a later date, and from a secondary pigmentation.

Dr. Gordon M. Holmes and Mr. R. A. Greeves communicated a paper on Flat Sarcoma of the Choroid, with Multiple Metastases. It was a case in which the trouble commenced with external rectus palsy, and later there was severe pain in the right forehead, and examination revealed considerable sensory loss in the distribution of the first division of the right trigeminal nerve. Still later there was complete loss of tactile sensibility, and partial palsy of all external muscles innervated by the right oculo-motor nerve. The pupils, however, continued to react well to light, but he subsequently developed marked optic neuritis. Death occurred 5½ years after the commencement of the symptoms. —Mr. Leslie Paton discussed the case.

Mr. R. A. Greeves read a paper on Two Cases of Microphthalmia, and Mr. Leslie Paton a paper on Papillœdema in Disseminated Sclerosis. In 100 cases Mr. Paton had met with five which showed evidence of past neuritis. In one case 18 months after the optic neuritis had been present in one eye there were normal fundi without atrophy and with normal visual fields, vision being 6/9 in one eye and 6/6 in the other. He related a number of cases supporting his thesis.

Lieutenant-Colonel R. H. Elliot, I.M.S., read a communication on Dressings and Antiseptic Methods in Ocular Operations. The paper was concerned with attention to minute details to ensure scrupulous cleanliness in operations; and incidentally the author criticised some thoughtless procedures which he had seen in certain clinics. Referring to the recommendation of Lieutenant-Colonel H. Herbert, I.M.S. (retired), for irrigation of the conjunctiva with 1 in 3000 perchloride, he said that since 1907 he (the speaker) had not had one case of post-operative panophthalmitis. —Professor Landolt, in discussing the paper, expressed the opinion that boiling cutting instruments spoilt the cutting edge, an important matter seeing that a clean-cut wound was very much more satisfactory than one which was not made with a very sharp instrument. He therefore used and recommended dry heat—viz., up to 150° F.—keeping the instrument in that for 20 minutes. He believed he had never had a case of infection from instruments. His practice was, when using atropine, to use a fresh ampulla each time. He objected to an irrigator.—Mr. Jessop referred to the danger of using long indiarubber tubes in connexion with operations; several which were bacteriologically examined at a large hospital were found to be teeming with micro-organisms.—Professor Straub pointed out that most of the infections at operations arose from the spread of organisms which were already resident in the eye. His practice was to carry out the sterilising and cleansing procedure on the patient for three days before operating.

Mr. C. Wray read a paper on the Treating of Dislocated Lens. He said he did not consider needling was a form of treatment of dislocated lens. If the lens were very much displaced, iridectomy might be the right thing to do, but he did not think it was generally sufficiently displaced to justify that procedure. If the natural tendency of the lens was to become dislocated, he did not hesitate to do couching.—The paper was discussed by Professor Landolt, Mr. Story, Mr. Priestley Smith, Lieutenant-Colonel Elliot, Mr. Rowan, Professor Straub, and Mr. J. Gray Clegg.

Friday morning was devoted to the subject of Post-operative Complications of Cataract Extractions. The discussion was opened by Mr. E. Treacher Collins, and he treated it chiefly from the pathological point of view. He first of all called attention to the difference noticed in the healing of extraction wounds after the different forms of incision made by different operators, and he described how some incisions healed much better than others. He greatly favoured the incision which aimed at the cutting of a conjunctival flap. If the wound did not heal readily it was possible for a down growth of epithelium to take place, and this might spread over the whole of the anterior chamber, and be the cause of blocking of the angle of the anterior chamber, and thus of causing a condition of glaucoma. He discussed the effect of delayed union of the posterior lip of the wound and the cause of striated opacities of the cornea after extraction. Prolapse of the iris causing a bulging cystoid scar sometimes led to a late suppurative condition of the uveal tract which might occur months or even years after the healing of the wound. Astigmatism varied enormously in amount after extraction, and largely depended on the healing of the wound and the way in which the flap was in apposition. Suppurative inflammation of the cornea was most often caused by the pneumococcus, but the frequency of this had been greatly diminished by aseptic precautions, as sterilisation of instruments. Thus in a series of Moorfields cases published in 1876 the percentage of eyes lost from this cause was 6·2. In another series published in 1894 it was 1·7, and in Mr. Collins's own cases done between 1900 and 1912 it was 1·15 per cent. No sterilisation of instruments was done at this hospital previous to 1883. He advocated the use of the galvano-cautery in such cases, and he had also seen good results follow the use of vaccines, but as other local treatment was always carried out it was difficult to say how much good really resulted from the injections. In some cases posterior synechia developed in quite quiet eyes, and these he did not look upon as being septic; in like manner non-septic "keratitis punctata," which was certainly non-septic, could often be found in cases running a normal course if these dots were really looked for. He thought it quite a fallacy to think that the mere presence of soft lens matter in the anterior chamber was capable of producing iritis, but when it was mixed with aqueous it certainly formed a very good nutrient medium for the growth of organisms if any were allowed to be present. With regard to the development of sympathetic ophthalmitis he had seen several cases which had greatly benefited by the use of salvarsan, and he also alluded to the information to be derived in dangerous cases by having a blood count done. He discussed in detail the way in which glaucoma was produced after an extraction or a needling of capsule and the ways of treating them. He finally dealt with expulsive hæmorrhage, detachment of the choroid, opaque membranes, vitreous opacities, and detachment of the retina.—Lieutenant-Colonel **HERBERT** dealt with the subject from the clinical side. He said that the most serious after-complication of cataract extraction was that due to infection. He strongly advocated the very thorough irrigation of the conjunctiva with perchloride of mercury, and gave statistics showing how in India suppuration became all but unknown after this was carried out in a thorough and systematic manner. The usual strength he used was 1 in 3000. This certainly had the drawback that it did irritate the conjunctiva and subsequently led to a further development of micro-organisms than would otherwise have been the case, though by this time the wound had healed; but it should be taken into consideration if it were contemplated to do a further operation within the first two weeks, such as very early needling. He was strongly in favour of making a large conjunctival flap with the original incision for the extraction.—Sir **ANDERSON CRITCHETT** considered that Mr. Treacher Collins had placed upon a firm pathological ground questions upon which the profession was previously in a condition of uncertainty. He described what he considered to be the best procedure in complicated cases of cataract where the iris had been drawn up into the wound or where there was a dense capsular membrane. No class of case required greater experience, and he discouraged the slightest empiricism, advocating eclecticism, adopting the procedure found suitable to each particular case.—Mr. **SIDNEY H. BROWNING** read an interesting communication on the subject, in which he said that out of hundreds of cases examined at Moorfields Hospital before the cataract operation only one case was pronounced bacteriologically clean which subsequently became infected after operation. Three of the 14 unsatisfactory cases during the last four years had been in eyes which had been reported unfit for operation, but were nevertheless operated upon. All these eyes were lost. Some of the chronic cases of low virulence responded to vaccine treatment, some yielded to salvarsan and neosalvarsan, He suggested that causes for sepsis should be searched for further afield than in the eye itself—viz., in the gums, nose, throat, &c. Many of the infections he had found to be endogenous, not arising in the conjunctival or lacrymal sac. The practice of bandaging the eye for 24 hours previous to operation and deciding whether the eye was fit for operation by the comparative absence of pus on the bandage he considered to be bad from a bacteriological point of view, for in several cases examined carefully the organisms present had increased during the time the bandage was in position, and some forms of virulent organisms were present after the bandaging which had not been detected before.—Mr. C. **KILLICK** described his results in 101 serial cases, one of which suppurated. During three years in his own practice he had had only three cases of suppuration after cataract extraction out of 1000 cases. One eye in each of these three cases was restored to sight. He also described the varieties of "after-cataract," and said he had had to needle 28 times in all his cases for capsular proliferation.—Mr. C. A. **WORTH** spoke of hæmorrhage occurring into the anterior chamber five days after the operation, and he regarded that as peculiar to the operation on the conjunctival flap; he had not seen it where the incision had been corneal, and it probably occurred after some movement on the part of the patient, not necessarily a blow. This hæmorrhage retarded convalescence. He had adopted a conjunctival flap in all cases and keeping the patient quietly in bed for a longer time than for corneal discission. He also spoke of the accident of vitreous coming forward into the anterior chamber through the discission of the membrane. At the time of the extraction he always divided the capsule straight across; he made no attempt at the V-shaped opening, so that in most of the cases there was an anterior capsule left in the line of the pupil.—Mr. A. W. **ORMOND** read notes of two cases in which post-operative complications occurred after removal of lens. Both were endogenous infections.—Mr. **STORY** said he had been able to assist some cases of wound infection by the application of the electro-cautery to the edges of the wound and by a subconjunctival injection of cyanide of mercury. He believed in the majority of cases of inflammation after cataract extraction it was an exogenous infection, and it had long been his practice before operation to make careful examination not only of the eye, but also of the nose and mouth. If there were many organisms operation was deferred, and the patient submitted to a cleansing and fortifying treatment.—Dr. G. F. **ALEXANDER** spoke of the great instruction he had received from operating in Lieutenant-Colonel Elliot's clinique at Madras, and related some of the impressions he had derived from the wealth of material available therein.—Lieutenant-Colonel **ELLIOT** spoke in high praise of Mr. Collins's contribution to this subject, and declared that there was no ophthalmologist for whose work the younger practitioners in India had a more profound admiration. He also thanked him for the generous terms in which he had acknowledged Colonel Herbert's valuable work in the same direction. He (the speaker) had himself worked hard for a number of years on the subject of post-operative astigmatism, and Mr. Collins's present paper had been most valuable to him. He supported Mr. Collins's remarks about the influence of traumatism on the appearance of post-operative opacities. Where there was a large lens which had to be delivered through a tight wound there was apt to be striated keratitis. For non-inflammatory cataract he used two needles; for inflammatory cataract he used the knife, and if that failed he opened the chamber; he did not cut the capsule, but cut the healthy iris.—Professor **LANDOLT** expressed his great satisfaction with the statistical contributions of the openers, and said his experience had led him to the same conclusions. One of the most dreaded complications, apart from sepsis, was prolapse of the iris. To avoid this he always performed iridectomy with the cataract extraction, excising the iris widely, often in two cuts, so that after the section it retracted by its own elasticity. If part of the iris were entangled in the scar he would cauterise it with the galvano-cautery, afterwards covering with a flap of conjunctiva. He had always been sceptical as to the use of the preliminary bandaging; and he proceeded on the assumption that no conjunctival sac was free from pathogenic germs. Moreover, danger of infection persisted so long as the wound remained open. He pictured it as a race between the development of noxious germs and the closure of the wound. If the eye were tied up 24 hours before operation the development of these germs was favoured and the patient's recovery handicapped. He did not agree with the use of strong antiseptics for cleansing afterwards, though in conjunctivitis he would even use nitrate of silver. He showed his forceps for the purpose of dealing with secondary cataract.—Dr. G. MACKAY asked whether some weaker preparation than 1 in 3000 perchloride would not do. He had given up strong solutions because of the frequency of posterior corneal opacities. His preparation of the patient consisted of regular douching of the conjunctiva with sterile saline or boric lotion. In this connexion argyrol was also useful, employed two or three times a day.—Professor UHTHOFF also described his methods and experiences in the operation, and was followed by Mr. THOMSON HENDERSON.—Professor STRAUB spoke of the chronic inflammation which commenced in the second week after operation, and said he had not seen this occur when the toilet after the operation had been well and carefully done. He also detailed his method for preventing squeezing of the eye, this squeezing sometimes accounting for the loss of the eye.—The PRESIDENT said they all realised that the essential necessity was the production of absolute local asepsis, or antisepsis, the most rigorous cleanliness of instruments, patient, and person. Most of the cases of sepsis he regarded as exogenous, but there were cases of endogenous infection. Cases such as Mr. Ormond related he considered to be gouty, using that term in its generic sense. He referred to the possibility of sepsis from the teeth and from metastatic inflammation. He related some cases.—The openers of the discussion briefly replied.

On Friday afternoon a clinical meeting was held at the Central London Ophthalmic Hospital, when the following cases were demonstrated and discussed.

Mr. F. A. JULER: 1. Hyaline Bodies on the Optic Disc. 2. Congenital Ophthalmoplegia.

Mr. LESLIE PATON: Congenital Malformation of the Disc.

Mr. M. S. MAYOU: 1. ? Tuberculous Mass in the Optic Nerve Sheath. 2. ? Inflammatory or Congenital Mass around the Nerve Head.

Mr. CECIL GRAHAM and Mr. LESLIE PATON: Cases of West's Operation for Lacrymal Obstruction.

Mr. TREACHER COLLINS: Concussion Injury with Rupture Extending Across the Optic Disc.

Mr. C. WRAY: 1. Coloured drawing of the "Rare Cases of Corneal Disease" shown at the last meeting. 2. Two cases of Ectopia Lentis. 3. Case of Intra-orbital Neoplasm. 4. Lenticonus. 5. Case of 6D. of Hypermetropic Astigmatism cured by the cautery: vision 6/6.

Mr. SYDNEY STEPHENSON: Case of Sympathetic Ophthalmitis treated by six injections of neosalvarsan.

Mr. R. R. JAMES: 1. Massive Tubercle of the Iris. 2. Crater-like Hole at the Disc, with Macular Changes.

Mr. G. COATS showed and described a case of Congenital Partial Paralysis of the Oculo-motor Nerve, with cyclical contraction and dilatation of the pupil. The condition was observed in the left eye of a girl aged 10, and had been present since birth. The signs of oculo-motor paralysis were: partial ptosis, divergence, abolition of upward, and limitation of inward and downward movement. The cycle of pupillary phenomena consisted of a relatively rapid contraction, followed by a more gradual dilatation. The movements were not strictly rhythmical, and movement of the eye to the right, whether on convergence or conjugately, tended to induce contraction and render the phase of dilatation more intermittent and less complete; relaxation of the internal rectus had the opposite effect, but the play of the pupil continued even when the adducted or abducted position was continuously maintained. During contraction the pupil was immobile; during dilatation it responded to light and consensually. In ordinary circumstances the stage of myosis was accompanied by a contraction of the ciliary muscle and by slight raising of the lid. The eye was astigmatic and amblyopic, the other being slightly hypermetropic. Some 19 cases of this affection had been recorded, most of them in recent years. Characteristic of the group was a partial third nerve paralysis, usually, but not always, congenital, and interrupted by periods of activity in the internal rectus, levator palpebræ, sphincter pupillæ, and ciliary muscle. The suggested explanation of Salus was stated and discussed—that during the repair of a lesion of the third nerve some of the axis cylinders sprouting from the central end made a kind of "false junction" and so connected a given nerve centre with a muscle or group of muscles not belonging to it. If, for instance, all the fibres which should go to the internal rectus were diverted to the sphincter, then an effort at adduction would result only in a contraction of the pupil, and a partial side-tracking of these fibres would produce partial phenomena of the same nature. This hypothesis, however, did not readily explain why the false junction should invariably take place between the internal rectus fibres (occasionally *also* the inferior and superior rectus fibres) and the pupillary and levator fibres—why, for instance, the attempt to look inwards was never associated with a movement upwards of the globe; something a little more haphazard might be expected in the case of nerve fibres finding their way at random through a mass of inflammatory material.

On Saturday morning Mr. THOMSON HENDERSON demonstrated and described a pressure gauge which he had devised for measuring changes in the intraocular pressure instead of the digital pressure in order to test the intraocular tension.

Mr. C. B. GOULDEN read an instructive paper on Optic Neuritis and Spinal Myelitis, describing a number of cases which illustrated the usual progress of the disease.—Mr. J. B. LAWFORD, who discussed the paper, described a case in 1884. He remarked that the profession remained as ill informed as to the causation of the disease as it was 30 years ago. He hoped a similarly careful investigation of future cases would be made as that by Mr. Goulden.—Dr. GORDON HOLMES related three cases of the condition, one of whom recovered completely after being as desperately ill as possible. In the cases which he had examined post mortem the most extensive lesion was in the chiasma or in the optic nerve. There was considerable disintegration of nervous substance. Axis cylinders remained practically intact. The actual infecting agent was not yet known.

Mr. G. T. BROOKSBANK JAMES read a paper on Iridosclerotomy in Glaucoma. Having referred to previous communications on the subject he described the operation that he adopted. A large conjunctival flap was turned down well over the corneal margin consisting only of the superficial part of that structure. An incision was then made transversely close up to the reflected conjunctiva, being about 1 mm. within the limbus. A second incision was commenced at one extremity of the first, and diverging somewhat finished close to the other extremity, and included about ½ or ¾ mm. of scleral tissue at this extremity of the incision. The anterior chamber was then opened by deepening the central portion of the first incision. After the aqueous had slowly escaped the incision was enlarged to its extremities. A repositor being used to free the flap from any deep attachments, it was separated through the length of the wound and turned outwards. A medium-sized iridectomy was performed and the conjunctival flap was then replaced. He claimed for the operation that the conjunctival flap was a great safeguard and was necessary to allow of filtration. The opening in the sclera was a chink instead of a hole and facilitated the escape of fluid all along the wound. The iridectomy was always satisfactory and he had never known impaction of the iris tissue. The safety of the operation was due to the position of the incision and to the fact that the aqueous escaped very slowly. Having compared the results of his operation with trephining, he far preferred the operation he had described for the permanent relief of tension. He showed some of his cases illustrating the method.

Dr. C. O. HAWTHORNE showed a number of Perimeter Charts taken from cases in which homonymous hemianopia was the principal or only evidence of intracranial disease. In his first group he placed cases of cardio-vascular degeneration with or without renal disease, the hemianopia here being due presumably to arterial obstruction or rupture. In a second group were described cases of homonymous hemianopia occurring in young women free from all evidences of cardio-vascular or renal disease but the subjects of anæmia or chlorosis, and in these cases it was argued that the hemianopia was probably due to venous or sinus thrombosis within the skull. Rarely a similar condition developed in epilepsy, and here also it might be possible to hold that sustained arterial spasm might lead to capillary and venous thrombosis, which, occurring in the visual tract posterior to the optic commissure, would be sufficient to account for the homonymous hemianopia.—The paper was discussed by Mr. BROOKSBANK JAMES, Mr. D. LEIGHTON DAVIES, Dr. ALEXANDER, Professor LANDOLT, Professor condition all cleared up.—Dr. Knowsley Sibley showed a girl, aged 19, who was born with Ichthyosis. Four other members of the family were *similarly* affected. There was *also* an eczematous condition of the right nipple, and an *areola* which was hypertrophied with oozing. The breast was painful. A section had been taken which resembled the description of an early stage of *Paget's disease*, but the age of the patient was against this.—Dr. R. Prosser White read a paper entitled "Some *Dermatological* Problems," in which he discussed the action of certain irritants to the skin which were responsible for trade dermatitis. He also mentioned a case of milk erythema that was set up in a child, aged 6 months, from simply touching the skin with cow's milk.—Dr. Griffith and Mr. H. C. Samuel joined in a lengthy discussion and Dr. Prosser White replied.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in Manchester on April 17th, Dr. J. H. Willett, the *President*, being in the chair.—Dr. W. A. MacKay (Southport) exhibited a post-mortem specimen of Ruptured Tubal Pregnancy, the symptoms suggesting irritant poisoning. Sixteen hours after a meal containing bloater paste the patient had severe abdominal pain, vomiting, and diarrhœa; she became collapsed and died five hours later. Post mortem a ruptured right tube with a *six weeks'* fœtus was discovered.—Dr. W. E. Fothergill (Manchester) exhibited a specimen of Perithelioma of the Ovary, about the *size of a fœtal* head, removed from a woman aged 38 years.—Dr. J. Oldfield (Leeds) exhibited four specimens of Mesothelioma—one in the uterus, forming a tumour of the size of a full-term pregnancy; *the second a pelvic mass consisting* of uterus, both ovaries, and a retrocæcal mass; the third in the ovary; and the fourth in the kidney.—Dr. Fothergill and Dr. D. Dougal (Manchester) showed a specimen of Aneurysm of the Internal Iliac Artery. Cæsarean section had been performed for contracted pelvis ten months previously, and the aneurysm was first noticed three weeks after this operation. There seemed to be no connexion between the two, and they were of opinion that the lesion was present before the patient came under their observation.—*Dr.* W. K. Walls (Manchester) exhibited a specimen from a case of Cæsarean section and Wertheim's *hysterectomy for Pregnancy*, with Carcinoma of the Cervix and *Double* Papillomatous *Ovarian* Cysts. The patient was seven *months* pregnant, with fairly advanced carcinoma of the cervix. *Both ovaries* were cystic and lined with *papillæ*, one being of the size of a fœtal head and the other of an orange.—Dr. Oldfield read the notes of three cases of Ovarian Tumour Obstructing Labour. One child was delivered by Cæsarean section; in the second case abdominal section was performed and the obstructing tumour removed, by which time the child's head was on the perineum, so was extracted with forceps; and in the third case the cord was prolapsed and only *feebly* pulsating, the child being delivered by craniotomy and the tumour removed *at a later date.—Dr.* H. Clifford (Manchester) *reported* a case of Concealed Accidental Hæmorrhage recently treated by him in which he performed Cæsarean section followed by supravaginal hysterectomy. The patient was in an exceedingly serious condition, being so anæmic and so collapsed that neither the incision in the abdominal wall nor that in the uterus bled at all. The patient made a good recovery.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Infirmary on April 21st, Dr. Sykes being in the chair.—Dr. F. W. Eurich gave a microscopical demonstration.—Dr. W. Mitchell gave a demonstration of X Ray Plates, showing particularly the size and shape and position of the stomach in health and disease. The plates were taken at varying intervals after a barium meal, and showed especially how long a time it takes for the atonic and dilated stomach of pyloric obstruction to empty itself of its contents.—Dr. J. R. Gilmour read a paper on Mental Disease from the General Practitioner's Standpoint. He regretted that general practitioners took so little interest in their mental patients. If the medical man would only examine his mental cases in the same way as he examined an ordinary medical case, Dr. Gilmour was convinced of the enormous benefit which would accrue not only to the patient but also to the practitioner. Many cases now sent to the asylum could very well be *treated at home* and the patient saved the objectionable stigma of having been an inmate of an *asylum*. Dr. Gilmour gave several very interesting cases illustrating this point, and showed how entirely wrong it was to send every patient with mental symptoms straight to the asylum without first investigating the cause of those symptoms. He pleaded strongly for the establishment of "half-way houses" or nursing homes, where mental patients could be treated *pending* a definite decision as to whether such patients really required asylum treatment. He felt convinced that many cases *in which a definite cause* for the symptoms could be found—e.g., *tumours* of the breast, acute appendicitis, pyorrhœa, cases following *influenza*, &c.—recovered permanently and completely, and that it was utterly wrong to cast the *slur* of the asylum on them. In conclusion, he tabulated mental diseases as far as they concern the general practitioner as follows: (1) infective—e.g., influenza, pyorrhœa, cholecystitis; (2) circulatory—e.g., middle age, *muscle* weakness, especially of heart; (3) biochemical—e.g., exophthalmic goitre, uræmia, diabetes; (4) *arterio-sclerosis*; (5) alcohol.—Dr. Eurich, in discussing the paper, agreed in the main with what Dr. Gilmour said, but pointed out the difficulties of carrying out a thorough examination on a *wildly* maniacal patient.

Reviews and Notices of Books.

Die Vitamine: ihre Bedeutung für die Physiologie und Pathologie, mit besonderer Berücksichtigung der Avitaminosen (Beri-Beri, Skorbut, Pellagra, Rachitis). Anhang: Die Wachstumsubstanz und das Krebsproblem.

Von CASIMIR FUNK, Cancer Hospital Research Institute, London. Mit 38 Abbildungen im Text und 2 Tafeln. Wiesbaden: J. B. Bergmann. 1914. Pp. 194. Price 8.60 marks.

THE author states that this publication is the first attempt at a representation of our knowledge about vitamines and avitaminoses. In addition to the author's own work and views it includes much that is fragmentary and also much that is purely hypothetical. Many facts are still wanting, but it is a step in the direction of elucidating the physiology and pathology of such diseases as beri-beri, scurvy, pellagra, and rickets. By the word avitaminoses, coined by the author, is understood what is called in English "deficiency diseases."

Beginning with beri-beri and experimental beri-beri in animals, the author points *out* that though this disease has keenly interested observers for the last 20 years, mostly in countries where rice formed the chief diet of the people, it is only comparatively recently that this disease in man and polyneuritis in fowls or pigeons have been known to be associated with the use of polished rice as the chief food. With the introduction of mechanical mills *and other* means for polishing rice in Eastern *countries* the disease increased. When in 1882 *Takaki introduced* a mixed diet for use in the Japanese navy beri-beri practically disappeared.[1] In *Java* in 1895–96 Vordermann proved that the disease was associated with, and was due to, the continued use of polished rice, while in 1897 Eijkman showed that in polished rice that part of the rice which protects from the disease is lost, while Fraser and Stanton showed that the protective substance *lies in the* surface layers of rice grain. Then *follows an account* of the geographical distribution of *beri-beri, its pathology*, and its *symptomatology* in its *atrophic*, paralytic, and dropsical forms.

The experimental production of the disease in fowls (polyneuritis) is next considered and illustrated by many photographs of fowls and pigeons. A long account is given of the author's experiments to isolate and determine the nature of the protective or healing substance—the vitamine—that occurs in the outer layers. Vitamines occur in many foods besides rice, and they have been specially investigated in yeast by the author. An account of his methods is given.

---

[1] THE LANCET, May 26th, 1906, p. 1451

Next the author deals with the scorbutus group, including experimental scurvy in animals and Barlow's disease, which are discussed on the same lines as in the case of beri-beri. The vitamines of milk are specially considered, and then the intimate relations between beri-beri and scorbutus are discussed. Pellagra and sprue are next considered, and then the prophylaxis, pathogenesis, and therapeutics of pellagra in the light of the vitamine theory. The consideration of rickets, osteomalacia, and spasmophilia occupies the fourth section. Disturbances of nutrition in infants are then passed in review and linked up with deficiency diseases. A short account is given of the chemistry of growth in plants with remarks on growth and the cancer problem, and the author brings his treatise to a close by a discussion of vitamines in their relation to the phenomena and doctrines of nutrition, metabolism, and internal secretions.

Altogether this is a most interesting and suggestive treatise—a pioneer work opening up many new fields of research of great practical importance, not only to inhabitants of the tropics, but to those who live in temperate climes as well. We hope the author will see his way to publish it in an English garb. The literature is fully given and is already extensive. With regard to recent contributions on the subject in THE LANCET, we may refer to Dr. Casimir Funk's own paper on "Studies of Growth: The Influence of Diet on Growth, Normal and Malignant," which appeared on Jan. 10th, 1914; to a paper on "Unpolished Rice and Beri-Beri," by Dr. Henry Fraser and Dr. A. Stanton in the same issue; to an annotation on March 21st; and to letters by Professor W. D. Halliburton (March 28th), and Professor Leonard Hill and Dr. Ralph Vincent (April 4th).

Minor Medicine: A Treatise on the Nature and Treatment of Common Ailments.

By WALTER ESSEX WYNTER, M.D., B.S. Lond., F.R.C.P., F.R.C.S. Eng., Physician to the Middlesex Hospital and Lecturer on Medicine in the Medical School. Second edition. London and New York: D. Appleton and Co. 1914. Pp. 275. Price 6s.

IN our review of the first edition of this work we expressed the favourable opinion we had formed of it, and a perusal of this edition has corroborated our previous impression.

Dr. Wynter has now prefaced the book by an "introduction" which contains many sapient and suggestive remarks. He points out the difficulty of steering a middle course between indispositions too trifling or familiar to deserve mention and those which already receive ample attention in more serious books on medicine. We entirely agree with him that still more formidable is the danger of including among trifling ailments phenomena which, though apparently of slight importance, may belong to really serious disease. He discusses some of the difficulties which may arise, and amongst other considerations points out that persistence or increase in any local sign or symptom suggests some underlying cause, and that the coincident occurrence of what is termed bodily illness goes far to confirm the suspicion of actual constitutional disease. He gives as an apt illustration the outbreak of warts, which in a young robust individual is a matter of small concern, but in an elderly person exhibiting cachexia and pigmentation may indicate that rare form of malignant disease, acanthosis nigricans. Dr. Wynter then proceeds to a survey of some points in the development, growth, maintenance, and decay of the human organism, which may be regarded as representing natural phases in the course of life, and he draws attention to the diet which is suitable at each age and to physiological changes which may possibly be exaggerated, so producing unnatural or morbid phenomena.

The general scope of the work remains as before, but the book has been revised and some additions have been made. It is a manual which will be found of value to medical men engaged in the general practice of their profession, for it contains, in a form that lends itself to easy reference, a large amount of information and numerous hints which are not met with in the usual text-books on medicine and therapeutics.

A Handbook for the Post-mortem Room.

By ALEXANDER G. GIBSON, D.M. Oxon., F.R.C.P. Lond., University Demonstrator in Pathology, Oxford, and Honorary Assistant Pathologist to the Radcliffe Infirmary, Oxford. London: Oxford University Press. 1914. Pp. 140. Price 3s. 6d.

THIS is just the handy little volume that the student should be encouraged to slip into his pocket when on his way to the post-mortem room. It is clear and terse and practical from beginning to end. No attempt is made to describe the pathological conditions met with. Instead the author has contented himself with a careful and lucid explanation of how each and every organ and structure can best be got at and removed for the purpose of complete investigation; how the various organs can best be examined after removal, and in each instance the chief points upon which attention should be focused; what to look for in the body cavities when emptied of their contents and how to examine the sense organs; how to make special necropsies, bacteriological and medico-legal; and—a somewhat important matter—how when the necropsy is completed the normal appearance of the body can best be restored.

We have nothing but praise for the matter contained in this small volume and the way in which it is presented, and regard the work as a useful addition to the Oxford Medical Series.

Materia Medica, Pharmacy, Pharmacology, and Therapeutics.

By W. HALE WHITE, M.D. Lond., Senior Physician to, and Lecturer on Medicine at, Guy's Hospital. Thirteenth edition. London: J. and A. Churchill. 1914. Pp. 695. Price 6s. 6d.

IN our review on March 9th, 1912, p. 654, of the twelfth edition of this work we remarked that Dr. Hale White's book has been found to be one of the very best treatises on these subjects which has been written, and we again endorse this opinion. It contains a vast amount of information which makes the book of value both as a text-book and as a work of reference.

In preparing this edition every care has evidently been taken to bring it up to date, and descriptions of several new drugs have been added, amongst which we note medinal, omnopon, and adalin. Medinal is sodium-veronal and adalin bromodiethyl-acetyl-urea, and both are stated to be useful hypnotics. Omnopon is a solution of the total alkaloids of opium as hydrochlorides, and freed from meconic acids, gums, and resins; it is of value in relieving purposeless coughing.

We once again express our appreciation of this excellent manual.

Ophthalmoscopic Diagnosis Based on Typical Pictures of the Fundus of the Eye, with Special Reference to the Needs of General Practitioners and Students.

By Dr. C. ADAM, Assistant at the Kgl. Univ. Augenklinik, Berlin. Translated by MATTHIAS LANCKTON FOSTER, M.D., Ophthalmic Surgeon to the New Rochelle Hospital; Member of the American Ophthalmological Society; Member of the American Academy of Ophthalmology and Otolaryngology. With 86 coloured pictures on 48 plates and 18 illustrations in the text. London: William Heinemann (Rebman, Limited). 1914. Pp. 229. Price 25*s.* net.

THE German edition of this book was reviewed in THE LANCET of Dec. 14th, 1912, and we were able to recommend it warmly as an excellent and cheap ophthalmoscopic atlas. Dr. Lanckton Foster is an excellent translator of German, and has carried out his part of the work well.

The author emphasises the real purpose of the book—that of serving as a systematic guide to diagnosis—and the text presents the subject matter from a different point of view to that of the ordinary text-book. It will be the more useful for this reason, and will form an invaluable aid to the student in the course of his clinical work. A few pages are devoted to the technique of the examination with the ophthalmoscope. Then follow in order the normal papilla and the normal fundus, conus and staphyloma, atrophy of the optic nerve, neuritis, the retinal vessels, the retina, and the choroid. The discussions of the various points of differential diagnosis are admirably treated, with frequent references to the excellent plates. In places the rather irritating method of question and answer, reminiscent of Mrs. Markham's history, is employed, but this is a venial fault. Sufficient attention is directed to the anatomical and pathological bases underlying the ophthalmoscopic appearances. Besides the brief general discussions each plate is fully described.

The work can be warmly commended, and Dr. Foster is to be thanked for rendering it more fully available to English-speaking students.

Ueber den Extrakardialen Kreislauf des Blutes vom Standpunkt der Physiologie, Pathologie, und Therapie.

Von Dr. KARL HASEBROCK, leit. Arzt des Hamburger Medico-mechanischen Zanderinstitutes. Mit 20 Abbildungen im Text. Jena: Gustav Fischer. 1914. Pp. 346.

THE author exposes an idea he has entertained for the last 20 years—viz., the great importance of the extracardiac circulation considered in its physiological, pathological, and therapeutical relations. As he is the chief medical officer of a medico-mechanical Zander institute, naturally this subject is one in which he takes a direct interest.

While admitting that the heart is, and must remain, the dominant apparatus of the circulation, the author lays great stress on the independence of the extracardiac circulatory apparatus. He argues for the existence of independent pulsatile movements of the blood-vessels, and he discourses on the existence of a pulsatile electrical action-current of the arteries—electro-angiogram—comparable to an electrocardiogram. According to him the effect of injurious agents falls first on the peripheral vascular system. There is a good deal of not too illuminating writing about aspiration at the extreme periphery of the vascular system. An account is given of the circulation in the capillaries, arteries, and veins, the significance of what is called the "diastole-systole" of the vessels as regards resistance and propulsion, the action of hormones, and of vaso-motor nerves. Attention is given to arterial blood pressure and its significance in nephritis and to some other diseases. Arterio-sclerosis is considered, and the remaining chapters deal with the significance of the extracardiac circulation in relation to "functional diagnosis," muscular work *in games, training,* and over-strain during severe muscular work, also in regard to gymnastic muscular work as a therapeutic cardiac agent. Finally, there is a short chapter on the neuroses of over-exertion and "fatigue of the circulation," "fatigue of the heart," and sclerosis.

Perhaps this book will interest most those who are concerned with the therapeutics of gymnastics and training generally.

LIBRARY TABLE.

A Short Practice of Midwifery for Nurses, Embodying the Treatment Adopted in the Rotunda Hospital, Dublin. By HENRY JELLETT, M.D., B.A.O. Dub., Master of the Rotunda Hospital, Dublin. Sixth edition. London: J. and A. Churchill. 1914. Pp. 508. Six coloured plates and 169 illustrations. Price 7*s.* 6*d.* net.—This edition has been carefully revised and brought into conformity with the existing practice of the Rotunda Hospital. A chapter has been added on obstructed labour, and in it the different causes of obstruction during labour are described. Little recommendation on our part is required of a book which is so well known as this small manual, and which has reached its sixth edition and fourteenth thousand. The book contains all that a nurse need know, and this is one of the best works of its kind.

Electro-pathology and Therapeutics. By ARTHUR E. BAINES and F. H. BOWMANN, D.Sc., F.R.S. Edin., &c. London: Ewart, Seymour, and Co. 1914. Pp. 120. Price 5*s.* net.—The first part of this book is stated to be a prefatory address on the nervous system in its relation to neuro-electricity. *The term* "neuro-electricity" is introduced, without definition or description of its meaning, into an account of the nervous system, which contains many inaccuracies and incorrect statements. The "neuro-electricity" is stated to be generated in the brain, while nerve currents are said to act on the ionised cell contents in the living portion of the body, and to be the cause of metabolic activity. The second part commences with a criticism of the results obtained by physiologists (the results are not *stated*) as *erroneous* and misleading. The deflections of an astatic mirror galvanometer are supposed to be caused by the "nerve currents," the amount of the deflection being altered in disease and the rapidity is said to enable the observer to *form* an estimate of the gravity of the disease. The "electro-pathology of inflammation," according to the authors, is the action of the temperature on the nerve sheath and possibly on the vessel walls, and the breaking down of the resistance of either or both, so as to cause a leakage or short circuit of neuro-electrical current in the part affected. The treatment described by the authors is the application of a fluid (its formula is not given) which has great penetrative powers, reaching the seat of the inflammation and stopping the leak—a fluid which can be taken internally and cannot fail to be of value in appendicitis and gastritis. The results of the authors' researches are presented to the medical profession and the general public. From what has been mentioned above, any criticism will, to qualified medical practitioners, be superfluous; but seeing that treatment of patients by electrical methods is so largely practised by people without medical qualification, it is regrettable that such teaching, plausible enough as it may seem to those who have little accurate physiological and clinical knowledge, should appear, and under such a title.

General and Practical Optics. By LIONEL LAURANCE. London: Published by the Author, Temple House, Temple-avenue. Second and revised edition. 1914. Pp. 363. Price 10s. 6*d.* net.—This book has been written by an optician for opticians. As such, it includes all the most valuable information on geometrical optics for the ophthalmic surgeon. It is accurate and well arranged. It collects in one volume many facts which must otherwise be sought in general treatises on optics, and which will often be found only with difficulty. The reader will require an elementary knowledge of mathematics to cope with the formulæ, but this should not debar the earnest ophthalmic student from attaining a thorough knowledge of so essential a branch of his subject.

Index Catalogue of the Library of the Surgeon-General's Office, United States Army. Authors and Subjects. Second series. Vol. XVIII. Tetamore-Tzschirner. Washington, 1912.—The eighteenth volume of this remarkable work, the assiduous and patient labour of which lays all medical scholars under a debt to the Government of the United States, contains 3865 author titles, representing 4117 volumes and 2693 pamphlets. It also contains 5223 subject titles in separate books and pamphlets, and 45,525 titles of articles in periodicals. The Surgeon-General's Library now contains 182,984 bound volumes and 320,343 pamphlets, and 110 new titles of medical periodicals have been added to the list of those indexed. The present volume bears the signature of Lieutenant-Colonel C. C. McCulloch, Junr., of the Medical Corps, U.S. Army, now librarian of the Surgeon-General's Office in succession to Lieutenant-Colonel W. D. McCaw. The most extensive article is that on Tuberculosis, which (with Tuberculin) occupies no fewer than 856 columns. Other extensive articles are those on Tetanus, which occupies more than 74 columns, Therapeutics (70 columns), Thrombosis (28), Thyroid Gland (51), Tongue (46), Tonsils (63), Trypanosoma and Trypanosomiasis (41), and Tumours (124).

MISCELLANEOUS VOLUMES.

OUR miscellaneous books for this week include an account of medical missionary work in India, a quasi-historical work dealing with hygienic matters in the past, a little book discussing some questions connected with blind deaf mutes, and additions to Shakespeareana and the table-talk order of book.

In the first named, *Jungle Days, Being the Experiences of a Woman Doctor in India* (London and New York: D. Appleton and Co. 1914. Pp. 227. Price 10*s.* 6*d.* net), Dr. ARLEY MUNSON describes how she felt a call to go to India to help her suffering sisters. Accordingly, having completed her medical studies in New York, she sailed for Bombay, and after a short stay at Sholapur was called to the post of medical superintendent of the Wesleyan Mission at Medak, Hyderabad. Dr. Munson does not say very much about her medical work, but writes pleasantly of the scenery and peoples she encountered in her various tours. One case which she mentions fills us with astonishment. On p. 64 she gives an account of a child of two, "whose eyelid healed well although it was gashed in half a dozen places by the horn of an angry bull. Mercifully the eye was spared." It seems to us that either the eyelid or the bull must have been of a size very different from the normal.——In *Le Passé Anecdotique* (Paris: Albin Michel), ERNEST LAUT discourses in a breezy way upon the hygiene (or absence thereof) in past times, and upon medical manners and customs from mediæval times down to 1830, when Victor Hugo, says M. Laut, left on record some scathing lines in an inn at Geneva as to its fleas, dirt, and general discomfort. In the eighteenth century it was common for inns to have two or three beds in a room, which travellers shared in common, a custom which gave rise to such situations as Sterne describes with his usual sardonic humour in the "Sentimental Journey." The condition of the streets in Paris and many other large towns was appalling as late as the end of the eighteenth century. Madrid had the worst reputation, as is shown by several travellers whom M. Laut quotes, and the same thing is testified to in a recently published work by Paul Fould, "Un Diplomate au Dix-Huitième Siècle" (Paris: Plon-Nourrit. 1914). The diplomat was Louis Augustin-Blondel, who, among other impressions of Madrid, has left the following: "Il n'y avait dans la ville ni chaise percée ni lieux." No wonder that further on he describes the town as "très malpropre."——In *Man's Miracle, the Story of Helen Keller and her European Sisters, from the French of Gerard Harry* (London: William Heinemann. 1914. Pp. 197. Price 3*s.* 6*d.* net), M. HARRY describes the life and practical new birth of Helen Keller, who became deaf, dumb, and blind at the age of 19 months, and of Marthe and Marie Heurtin, of Poitou, who were born deaf, dumb, and blind. M. Harry argues, from the wonderful results which careful teaching has achieved in these sadly afflicted beings, that in humanity there is some "invisible mental spring" which does not exist in the lower animals. As to the Creator of this spring he will not give an opinion. But to many minds the case of Helen Keller, and still more of the two Heurtins, will go to prove the existence of that "particle of Divine breath" mentioned by Horace, of that "sense sent down from the heavenly citadel," of which Juvenal talks in the noble close to his XV. Satire. In the book just discussed we see how beings apparently completely isolated, except by touch, from their fellows can be taught, made able to communicate with those around them, and how their higher faculties can be nurtured and used.

Lovers of Shakespeare—and surely where shall they be found more numerous than in the profession which beyond all others holds fast to the rule, *nihil humani a me alienum puto ?*—will gratefully welcome the posthumous publication by his daughter, Miss Rosaline Masson, of Professor DAVID MASSON'S "Shakespeare Lectures," which formed part of his professorial course on English literature at Edinburgh University. *Shakespeare Personally* is the title of the book (London: Smith, Elder, and Co. 1914. Pp. 242. Price 6*s.*), and it is an answer, to quote Professor Masson, to "that extreme compliment which it seems to be the whim of human nature to pay, at some time or other, to each one of those few personages of the past, the dimensions of whose existence have approached the enormous"—viz., that "enormously great existence is inconceivable except as non-existence." Professor Masson combines the actual knowledge of Shakespeare from external sources—and it is not a little greater than is commonly believed—with the portrait that may be conceived of him through a careful study of his writings, and succeeds in presenting us with a picture in which all the parts are complementary and in harmony. He traces the progress in Shakespeare's moods—first, the "Romeo-Proteus-Biron" mood, compounded of the passionate impetuosity, the all-for-love recklessness of Romeo, the instability and variability of Proteus, the wit, irony, and sharp-sightedness of Biron, characteristic of the centrifugal character of youth; then the "Jaques-Hamlet" mood, which combines the moralising and sadness of Jaques with the speculation, self-communings, and inaction of Hamlet, the centripetal reaction from the preceding; the "high-tragic" mood, envisaging the high tragedy of tremendous moral realities of passions, fates, and frenzies of the full-grown man with its reactionary subjectivity of the "Coriolanus-Timon" mood, the mood that is apt in later middle age to follow the aggressive zeal to right this topsy-turvey world—the mood expressed so forcibly by Horace, *Odi profanum vulgus et arceo*, sick of the fruitless turmoils of the fickle multitude; and finally the "Prospero" mood, the balanced judgment of mature experience, viewing from the heights, with expanded view and more enlightened understanding, the "alarums and excursions" in the plains below. Survey follows of Shakespeare's "recurrences"—repetitions of word, phrase, verbal or formal tropes, ideas and sentiments—and "fervours"—magnificent bursts of expression, which render Shakespeare the great fount of quotation, the armamentarium of the declaimer. The volume closes with an analysis of Shakespeare's self-revelation in the sonnets. Altogether a noteworthy study.——*Pot Pourri Mixed by Two* (London: Smith, Elder and Co. 1914. Pp. 456. Price 6*s.* net), by Mrs. C. W. EARLE and Miss ETHEL CASE, is a volume of discursive correspondence between two amiable ladies, arranged in 12 articles, one for each month of the year, every article consisting of a letter from each correspondent. The book would have been the better for the services of a judicious editor. It contains much that is good sound sense, a great deal that is very interesting in the table talk way, but unfortunately not a little that is rather silly. It may be described as a package of mental sandwiches, the insides of which are "scientific diet," vegetarianism, and total abstinence from "alcohol and other stimulants, especially tea" (p. 34), the substantial covering of the sandwich consisting of botanical and other "nature studies," and the garnishings of such aromatics as poetical selections of unequal quality, and historical, archæological, and travel notes. As an example of balanced good sense (and there is plenty of such in the book) may be cited the very thoughtful views on the position of the "caged daughters." But above all, reference must not be overlooked to the excellent collection of vegetable recipes, at the end of each month, selected with due reference to those vegetables that are then in season. It is by no means necessary that one should be a vegetarian to appreciate adequately these excellent recipes.

JOURNALS AND MAGAZINES.

Quarterly Journal of Experimental Physiology. Editors: E. A. SCHÄFER, W. D. HALLIBURTON, C. S. SHERRINGTON, E. H. STARLING, and A. D. WALLER. Vol. VIII., No. 1. London: Charles Griffin and Co., Limited. 1914. Pp. 102. Price 7*s.* 6*d.*—The Self-regulation of the Acidity of the Gastric Contents and the real Acidity of the Gastric Juice, by Professor W. Boldyreff (Kasan). A sharp distinction must be drawn between the acidity of the gastric juice itself and the acidity of the gastric contents. The author finds that the acidity of freshly secreted gastric juice is constant (0·5 per cent. HCl). In the gastric contents, however, this acidity is rapidly lowered to a level which oscillates between 0·15 to 0·2 per cent. HCl, and the same thing happens when any acids foreign to the stomach are introduced into it. The interesting point is the mechanism by means of which this "levelling" result is brought about. The partial neutralisation appears to be due to the reflux into the stomach of alkaline juices from the duodenum, the pancreatic juice being the most important factor. The mechanism for maintaining the optimum level of acidity (0·15 to 0·2 per cent. HCl.) the author calls "the self-regulation of the acidity of the contents of the stomach."—The Nitrogen Excretion of Fasting Sheep, by Andrew Hunter. The Influence of Early Removal of the Thyroid and Parathyroid Gland upon Nitrogenous Metabolism in the Sheep, by Andrew Hunter. These two papers must be taken together. In the first the author seeks to determine the distribution of nitrogen in the urine of normal sheep, upon which it appears there are practically no data of value recorded in the text-books. For the second article the author made use of the thyroidectomised lambs used by Sutherland Simpson.[1] The author finds that sheep deprived at an early age of thyroid, and somewhat later of parathyroids, (1) excrete during a fast rather more nitrogen and rather more purin derivatives in relation to body weight than do normal animals, and that they are liable to succumb very early to the effects of inanition; (2) they excrete while fasting urine which is generally acid and never alkaline; (3) they invariably react to the withdrawal of food by the excretion of creatine in excess of creatinine and have a degree of sugar tolerance which is almost certainly above the normal.—The Nervous Mechanism of Micturition, by F. J. F. Barrington. This is a very elaborate paper, in which the author first describes the peripheral nerves to the bladder in the cat. It is illustrated by many figures and some X ray photographs of the bladder after filling the bladder with a warm 20 per cent. solution of colloid silver. The cats, all females, were anæsthetised. The tonic influence of the nervous system on the bladder and urethra is described and experiments are cited. Reflex micturition and interference with micturition by nervous lesions are next described. It appears that in the cat micturition is a highly specialised act. The bladder is relatively very large, and micturition occurs infrequently—once or twice in 24 hours—and urine never escapes from the urethra apart from micturition. The effects of division of the peripheral nerves, division of the sacral posterior dorsal roots, transection of the cord between the seventh and twelfth thoracic roots, were then studied, and finally the mechanism of closure of the urethra. It is generally stated that micturition is dependent on the integrity of a centre in the lumbo-sacral region of the cord and on the connexions of this with the bladder and urethra, and that micturition takes place when this part of the cord is isolated from the parts of the central nervous system above it. In the cat after division of the sacral posterior roots micturition is permanently abolished. There seems to be no mechanism for this coördinate act existing below the lower thoracic region.—M. Dresbach describes an Improved Form of Apparatus for Perfusion of the Excised Mammalian Heart.—The Motor Areas and Pyramid Tract in the Canadian Porcupine, by Sutherland Simpson. In a historical introduction the author briefly describes the course of the pyramid fibres in the primates, carnivora, ungulata, cetaceæ, marsupialia, insectivora, cheiroptera, and rodentia. Six full-grown porcupines were used for his experiments. After being anæsthetised the position of their cerebral motor areas was determined, and then the results of a typical extirpation experiment are discussed. In the porcupine there are four pyramidal tracts entering the cord—the crossed dorsal pyramid tract, the crossed lateral pyramid tract, the direct dorsal and the direct ventral pyramid tracts.

Brain: a Journal of Neurology. Edited by HENRY HEAD, M.D., F.R.S. Vol. XXXVI., Part 2.—This number appears soon after the last, and it contains four papers of much interest. The first is by C. T. Van Valkenburg, on the Corpus Callosum, with experimental and pathologico-anatomical researches on this part of the brain. The reader interested in the subject must be referred to the article, which does not easily lend itself to abridgment.—Dr. Saunders contributes an article on the Sensory Changes in Friedreich's Ataxy, in which he shows clearly that sensory changes, slight but distinct, are much more common in the disease than has hitherto been recognised.—The third article by Dr. Fildes and Dr. McIntosh is on the Application of the Wassermann Reaction to Neurology, and the technique described is well worth the careful attention of all neurologists.—The fourth article on the Bulbar Nuclei, with special references to the existence of a salivary centre in man, has already been the subject of an annotation in these columns. The present number of *Brain* is quite up to the high standard we have been taught to expect from this journal.

American Journal of Roentgenology.—We note that the American Roentgen Ray Society has decided to issue its official publication as a monthly periodical instead of quarterly as formerly. It has seemed, in a country where radiology has made such rapid and brilliant strides, more or less anomalous, that no monthly journal should be forthcoming, and in congratulating the society upon their courage in filling this gap in current medical literature we may express the opinion that the step is one that has every prospect of success. The monthly issue began in November last under the editorship of Dr. P. M. Hickey, of Detroit, with Dr. F. C. Zapffe, of Chicago, as associate editor. The first number is a memorial to the late Dr. Lester Leonard, one of the most recent martyrs to the baneful influence of the X rays, and to whose untimely death we had occasion to refer in these columns. It will be remembered that Dr. Leonard was selected as chief reporter on the radiography of the stomach and intestines at the International Congress of Medicine in London last August, and his report forms the chief part of this number.—In the November issue there are papers on the Treatment of Uterine Fibroids and other Gynæcological Conditions, by Dr. A. F. Holding and Dr. G. E. Pfahler, among others. The new X ray tube is described by the inventor, Mr. W. D. Coolidge, and some notes on its practical application are given by Dr. Lewis Gregory Cole in the January number.—In the February issue there is an interesting contribution on the Possible Relation between the Pituitary Gland and Epilepsy, by Dr. G. C. Johnston, of Pittsburg. These are only a few of many interesting and valuable articles to be found in this valuable journal. Several of a more technical character but of the highest importance to radiologists are also given; these deal with such questions as X ray measurement, management and control of X ray tubes, the use of intensifying screens, and other subjects of a similar nature. The journal is printed on a specially good paper with a clear type that is a pleasure to read. The excellence of the illustrations calls for special comment. They are from half-tone blocks, in the preparation of which a very fine screen has been used, with a final effect that is very pleasing. We also notice that many of these are the same as the original negatives, in that the bones, for instance, are white, not black as in a print or other reproduction. If this can be done with less, or at least no more loss of fine details than in the more usual reproductions, it is probable that the change will be welcomed by radiologists who are accustomed to examine the original plates. The innovation is a noteworthy one, and it will be interesting to see how far it will become popular. This journal can be recommended to radiologists, who will be well advised to include it among those they receive regularly.

---

[1] *Quarterly Journal of Experimental Physiology*, vol. vi., 1913, and THE LANCET, June 14th, 1913.

British Dental Journal.—The issue for April 15th contains a thoughtful paper by Mr. Alan Forty on Some Ideals of Surgery in Dental Operations. He points out that many operations on the teeth are carried out with a total disregard of their effects on the tissues and their probability of causing sepsis.—There is a paper on School Dentistry, by Mr. C. F. Moxley, in which he gives a record of the work carried out at the Birmingham School Dental Clinics. Over 16,000 extractions were carried out, a little less than one-fifth being under anæsthetics, and over 8000 teeth were saved by filling.—Mr. Hopewell Smith records a case in which the left maxillary canine erupted posterior to the second premolar.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON).—A course of lectures on tuberculosis will begin at this hospital on Monday, May 11th, and will continue during the summer session.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—The fourth annual general meeting of this guild was held recently in the library of University College Hospital Medical School, Viscountess Bryce in the chair. Dr. Mary Scharlieb, honorary treasurer, submitted the balance sheet, and strongly urged the needs of the educational fund which aims at enabling children who are beneficiaries to make a good start in life. In the absence of Lady Tweedy, chairman of council, the annual report was read by Sir John Tweedy. The report states that the formation of new branches, the increase in the number of subscribers, and the keenness with which the work is carried on are highly satisfactory. The objects of the guild are to help the Royal Medical Benevolent Fund by obtaining additional subscriptions to that fund and by making it more widely known; also to assist distressed members of the medical profession, their wives, widows, and families, who are beneficiaries of the Fund, by personal service, provision of clothing, and help in other directions. The adoption of the report and balance sheet was moved by Lady Bryce, seconded by Sir Rickman Godlee, and carried unanimously.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

LAXAMEL.

(MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

Laxamel is an almost transparent jelly containing, according to our analysis, as much as 68 per cent. by weight of pure liquid petroleum. This amounts approximately to 80 per cent. by volume. It is quite pleasant to take and is attractive in appearance. Further analysis showed the presence of 11·63 per cent. of sugar and 6·6 per cent. moisture. There was no appreciable quantity of mineral matter present. The combination is designed for the use of patients who have a difficulty in taking raw oil, and it provides, of course, the well-known laxative effects of petroleum.

BIOMALZ.

(MESSRS. PATERMANN BROS., REGENT HOUSE, KINGSWAY, W.C.)

Biomalz is a fluid malt nutrient reinforced with the addition of calcium glycerophosphate. It presents all the nutritive properties of a well-made malt extract. Thus, besides containing malt sugar, there is present also a noteworthy proportion of soluble proteins. According to our analysis the total proteins amounted to 4·26 per cent. This is slightly in excess of the amount of protein contained in milk. Further examination gave the following results: Moisture, 37·83 per cent.; mineral matter, 1·48 per cent.; malt sugar, 44·44 per cent.; and dextrin, 11·99 per cent. In addition to phosphate of potassium always found in malt extract the presence of glycerophosphate of lime was established. On removing the ordinary phosphates with lime water glycerophosphate was found in the filtrate. The preparation is an easily digested food, while the presence of glycerophosphate supplies an approved aid to healthy nutrition.

ISTIN.

(THE BAYER COMPANY, LIMITED, 19, ST. DUNSTAN'S-HILL, LONDON, E.C.)

Istin is described as a synthetic laxative which is closely related to the active cathartic principle of rhubarb or senna. It occurs in the form of yellowish brown tablets containing from 2½ to 7½ grains. A characteristic chemical reaction of istin is the production of a crimson colour with ammonia. It is stated that the action of istin is entirely confined to the large bowel and consists in the stimulation of peristalsis exclusively in that region. It is reported to assist after one dose in restoring normal action.

THE CHANCELLOR GENUINE PURE GRAPE BRANDY.

(MESSRS. H. R. WILLIAMS AND CO., 6, LIME-STREET, LONDON, E.C.)

We have submitted this brandy to analysis, and the results support the claim that it is a pure grape spirit. It is a brown brandy with a matured flavour. Although not produced in the Cognac district, it possesses similar characteristics to the products of the Charente. It is mellow and free from crude products. It contains according to our analysis a maximum of ethers—namely, 105 parts per 100,000 parts of alcohol present. Doubtless its peculiar fragrance is due to some extent to these and allied bodies. Other secondary products were as follows: aldehyde 10·70, furfural 0·54, and higher alcohols 217 parts per 100,000 parts of alcohol. The strength of the spirit amounted to 46·59 per cent. of alcohol, and the total extractives were 0·65 per cent. The acidity of the brandy was inappreciable. It comes well out of comparison with the matured spirit produced from wine distilled in the Cognac district.

SECWA.

(CASEIN, LIMITED, BATTERSEA, LONDON, S.W.)

We find that secwa is correctly described. It is a yellowish-white powder obtained from whey by a special process which, while eliminating the water, leaves the product "live." That is to say, the enzymes are not killed and the milk albumin is not coagulated. Thus a solution of secwa in water on the addition of a little acid gives on heating an abundant coagulum of milk albumin. This, of course, is a valuable protein constituent of milk, and the occurrence of it in a relatively larger quantity in human milk is said to account for the increased digestibility of human milk compared with cow's milk in infant feeding. Our analysis of secwa gave the following results: Moisture, 2.00 per cent.; mineral matter, 9·00 per cent.; milk albumin, 14·50 per cent.; milk sugar, 74·50 per cent. There were only traces of fat present. Secwa is a sound preparation on scientific lines and should have obvious uses in special dietetics.

HEXANATRIN.

(MESSRS. CORBYN, STACEY, AND CO., LIMITED, BRUNTON'S WHARF, 673, COMMERCIAL-ROAD EAST, LONDON, E.)

Hexanatrin is a definite crystalline compound of hexa-methylene-tetramine and acid sodium phosphate. The idea of introducing acid sodium phosphate is to increase the acidity of the urine so that a maximum of latent formaldehyde is set free from the amine. There is thus claimed for the compound an increased power of killing infection. In other words, it is more active and rapid in its action used as an urinary antiseptic than hexa-methylene-tetramine alone.

STERILISED NATURAL MILK.

(NESTLÉ AND ANGLO-SWISS CONDENSED MILK COMPANY, 6 AND 8, EASTCHEAP, LONDON, E.C.)

We found the specimen of this milk which was submitted to us to be in excellent condition and perfectly sweet and fresh tasting. There were no preservatives present, and the milk kept sound for several days after opening. Its composition according to our analysis was as follows: Fat, 3·57 per cent.; casein, 3·68 per cent.; milk sugar, 4·75 per cent.; mineral matter, 0·70 per cent. This analysis evidences good quality, and the milk when taken from the tin was a perfectly homogeneous fluid with no trace of separated solids.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of the Governors and General Council of King Edward's Hospital Fund for London to receive the accounts and the report of the General Council for the year 1913 was held at St. James's Palace on April 30th, when the Duke of TECK presided.

Lord ROTHSCHILD, the honorary treasurer, in presenting the account of receipts and expenditure and the balance sheet for the year ending Dec. 31st, 1913, said the total investments of the Fund now exceeded £2,000,000.

The Duke of TECK moved the adoption of the accounts, and the resolution, having been seconded by Lord IVEAGH, was carried unanimously.

Sir SAVILE CROSSLEY, the honorary secretary, presented the draft report of the Council, which stated that the total receipts for the year 1913 were £187,704 18s., made up as follows: donations, £5810 0s. 6d.; contributions to capital, £2346 7s. 10d.; annual subscriptions, £26,187 17s. 9d.; contribution of the League of Mercy, £14,000; from the Lewis estate, £9092 4s. 3d.; legacies, £48,022 1s. 3d.; interest from investments, including property not yet transferred to the Fund, £82,046 6s. 5d.; together with £200 from the trustees of the Bawden Fund. The amount distributed was £157,500, being the same as in 1912. Of this sum the hospitals received £151,000, while the remaining £6500 were distributed amongst consumption sanatoriums and convalescent homes taking London patients. The £151,000 allotted to the London hospitals was directed to be applied as follows: £109,350 to general purposes and maintenance, £6000 towards the liquidation of debts on maintenance account, £1500 to an amalgamation scheme, and £34,150 for additions and improvements to hospitals and their equipment. Of the £6500 given to consumption sanatoriums and convalescent homes, £3800 were allotted in consideration of the allocation of beds for patients to be sent from certain London hospitals. His Majesty the King had continued his annual subscription of £1000, while Queen Mary, Queen Alexandra, the Prince of Wales, and many other members of the Royal Family had also liberally supported the Fund. The list of contributions included annual subscriptions of £5000 from Mr. Walter Morrison, £4000 from the Drapers' Company, £1000 from Mr. William Waldorf Astor, and £1000 from the Merchant Taylors' Company, besides three anonymous donations each of £1000. The legacies received during the year included £25,000 from Sir Julius Wernher, £8471 6s. 4d. on account of the bequest of Lord Lister, £6000 from Mrs. Batchellor, £4622 19s. 4d. from Sir William Dunn, Bart., and £1000 from Mrs. Emma James. In addition to the legacy of £25,000 from the late Sir Julius Wernher, the Fund received securities to the value of £269,644 7s. 2d., being a first instalment of his further legacy left to the capital account of the Fund of one-twelfth of the residue of his estate. A bequest from the late Mr. A. H. Harman, consisting of ground rents amounting to £1382 3s. per annum, was in course of transfer to the Fund at the end of the year. The total amount received in donations and subscriptions as compared with 1912 showed, excluding contributions to capital, a decrease of £5154. Legacies, however, showed an increase of £36,584 9s. 9d. as compared with 1912, or of £9352 14s. 5d. as compared with the average of the five years 1903 to 1912. The annual statistical report on the expenditure of London hospitals during 1912, issued in August, 1913, showed that the cost of working at hospitals had increased since the previous year by about £22,000.

The Duke of TECK, who moved the adoption of the report, read a letter from the King deploring the loss sustained by the death of Lord Strathcona and other benefactors of the Fund, and referring also to the deaths of Sir Trevor Lawrence and Sir Julius Wernher, the munificent bequest of the latter of whom would, by increasing the permanent income of the Fund, do much to ensure the annual distribution against the danger of possible reduction which seemed a year ago to be threatening.

The SPEAKER of the House of Commons seconded the motion, which was carried unanimously.

Sir WILLIAM CHURCH, chairman of the Distribution Committee, moved the adoption of a report of that committee upon the amalgamation of the Hospital for Diseases of the Throat, Golden-square, and the London Throat Hospital, Great Portland-street. The committee recommended that out of the grants of £20,500 promised and set aside for a general amalgamation the following grants be made and promised towards the present partial scheme—namely, a capital grant of £10,000 and an annual maintenance grant (subject to the usual annual inspection) of £900 a year for five years.

The motion was seconded by Mr. FREDERICK M. FRY and carried unanimously.

Other business having been transacted the meeting terminated with a vote of thanks to the chairman.

WHAT EVERY DOCTOR REQUIRES

is insurance against all the risks of his Profession. The ideal Policy is one which

1. Is permanent up to age 65.
2. Covers all sickness and accidents.
3. Gives cover immediately on payment of premium.
4. Provides for permanent as well as temporary breakdown.
5. Grants benefits at the lowest rates combined with security.
6. Gives generous bonuses.

The above are given by the MEDICAL, SICKNESS AND ACCIDENT SOCIETY, the Medical Man's Society.

CLAIMS PAID,	FUNDS,

The Budget and the Medical Profession.

THE Chancellor of the Exchequer made his Budget statement in the House of Commons on Monday last and revealed a financial condition of the country that has been realised with mixed feelings, the enormous value of the national resources being counterbalanced by the unprecedented demand upon those resources. We do not attempt to analyse his statement from the standpoint of the financier or the statistician, but propose only to call attention to the features of it which must have particular interest for our readers in the medical profession. How far Mr. LLOYD GEORGE'S intentions are instinct with wide-eyed patriotism and how far they are the offspring of deliberate attempts to win the support of the many by the exploitation of the few can be learned from the columns of the daily press. But if we read the press of one party we learn one thing, and if we read the press of another party we learn another thing, and the net result of such clarification of Mr. LLOYD GEORGE'S alleged obscurity is not informing.

There are designs in the Budget statement which are sure of the approval of the medical profession whatever the party politicians may say of them. The proposal that further and substantial aid should come from the Exchequer to mitigate the burdens put upon local authorities, in their attempts to meet the obligations incurred under legislation to carry on local government, will be regarded by fair-minded people as a move in the right direction, and will receive the endorsement of sanitary authorities. They will be in no trouble to criticise the methods introduced for raising the sums of money required in the indicated direction; it is a case of *non olet pecunia*. The finding of substantial sums, amounting in all to £1,250,000, in aid of the work of the National Insurance Act, will be approved as a whole. The establishment of local clinics to assist panel practitioners, the organisation of health lectures, and the control of malingering (which will require very discreet management), are legitimate outcomes of the working of the Act. That expenditure in suppressing cattle disease should be borne by the Exchequer will seem just, knowing with what difficulty this expenditure has sometimes been met by some localities; and it is good to learn that certain laggard or impoverished counties will be assisted to discharge their duties under the Mental Deficiency Act. The additional contribution from the State towards the maintenance of proper machinery for the promotion of national health and the well-being of the community will be welcomed. The intention will be applauded to provide local authorities with assistance in their endeavours to clear slums and provide better housing accommodation, to deal with the tuberculosis problem, to train an adequate supply of nurses, and to set up laboratories in which can be reinforced the efforts of medical men desirous of fighting disease in a scientific manner. These things are an adjunct to, or an elaboration of, the plans advocated by all our sanitarians; and however the money is raised, so long as the mere raising of it does not paralyse efforts of equal or greater value to the community, we must welcome such projects.

But members of the medical profession have to regard the Budget from the business point of view. As citizens they will take a substantial share in the burden of finding the money whose destination is so worthy. The new graduation of the income-tax in each of its forms cannot be other than irksome to the medical profession. Earned incomes up to £1000 are not interfered with, but from that point the figures are: £1000 to £1500, 10½*d.*; £1500 to £2000, 1*s.*; £2000 to £2500, 1*s.* 2*d.*; £2500 to £3000, 1*s.* 4*d.*; above £3000 and on all unearned incomes, 1*s.* 4*d.* Thriving medical men in every branch of the profession will be affected by the imposition of the higher rate, anyhow between £1000 and £2000; while the raising of the tax on unearned incomes from 1*s.* 2*d.* to 1*s.* 4*d.* will fall particularly hard upon them as investors, because the investments of medical men almost invariably represent their earnings and not their inheritance. The lowering of the line at which super-tax has to be paid, from £5000 to £3000, may only catch the very successful class among us, but hitherto most of these have escaped. The fact, however, that the first £2500 of these large incomes will be exempt from the charge will mitigate the circumstances to the majority of those affected. The medical profession is as ready to pay a high price for a proud citizenship as any section of the community, but it would not be difficult to show that this country is steadily becoming a very expensive one for the professional man. His burdens grow.

◆

The Narrow Way to Medical Research.

THE reports of the Royal Commission on University Education in London, Mr. ABRAHAM FLEXNER'S Report on Medical Education in Europe, Sir WILLIAM OSLER'S pronouncements on several occasions, and articles in our own columns have of late in different ways brought the academic ideal in medical education to the forefront, and the consideration of it has brought forth many weighty documents. An outstanding principle, that the teaching of a subject such as medicine in all its branches is inextricably bound up with continued research into the scientific problems that progressively unfold themselves, is now fully recognised and is acted on so far as the underlying sciences, both physical and biological, are concerned, but it is not so generally conceded that the same is equally true with regard to medicine itself.

But clinical research can be carried out properly only in an adequately fitted hospital with the necessary laboratory accommodation attached. In this country great public hospitals have for their objective the treatment and care of the sick individual, upon which clinical teaching has in process of time become engrafted by men whose ultimate aim has always been a distinguished career in practice. That up to a certain point these men have nobly fulfilled their secondary task of medical education is amply shown by the general high average standard of competence of the entire body of the British medical profession. That they have further contributed largely—very largely —to the extension of the domains of medical science the history of medicine amply testifies. But as conditions change so must we change with them, and the foreign possessions, so to speak, of the empire of medicine have now become so extensive that they can no longer be administered by those who *sit at home*. *A new race is demanded* which shall go forth into the new possessions, leaving old ties, old familiar aims and pursuits, and the life of the old-established communities behind, there to continue and extend the work in entirely new surroundings and by other means.

The need *for* an extension of medical research being admitted, what are the needs *of* medical research? This question has recently received an exposition and a suggestive answer in a weighty communication to the *Morning Post*.[1] Therein an anonymous writer, under the pseudonym of "Junior" (whose identity, however, may be shrewdly suspected by those who can read the internal evidence of authorship between the lines), speaking from an experience of ten years' engagement in medical research, for six of which it has been his chief object in life, lays down that the primary function of the research worker in medicine "is to supply the practising hygienist and physician with new knowledge of disease; to advance the science of prevention and the art of practice by the whole means in his power." He seeks; finding, he teaches; he teaches the facts he finds; he shows how his new facts link with older knowledge. There ends his task. The very temperaments required respectively for research and practice are opposed—though in rare instances, it is true, they are found combined in a single individual. For the researcher the spirit of hesitancy, of careful and prolonged questioning, of checking, if need be retracing, his steps is imperative, for thus alone will he avoid the pitfalls of premature conclusion. For the practitioner, on the other hand, that way madness lies. For him in most cases the paramount duty is to act—to apply promptly the knowledge he has acquired, groping his way only when he must, cutting across country, relying on his knowledge of the roads when he can, even on his instinct if necessary, so that he may arrive at his destination in time.

The obvious inference is that medical research, in place of being a subordinate occupation, a sort of apprenticeship for certain junior members of the profession, as is the frequent case at present, should constitute a career in itself; it should be an introduction not to practice, but to further research and to special teaching, calling for particular training and intensive study, an intimate knowledge of technique, and above all encyclopædic acquaintance with relevant facts garnered by the allied sciences. If that course were pursued the articles in medical publications would teem less frequently than at present with statements contradictory of settled physiological or physical teaching. At present such workers are for the most part young men on the waiting list of the various hospitals; consequently they have no wards in which to study, for these are all in the hands of their seniors, who have attained or are well on the road to an objective altogether different from that of research—viz., lucrative practice. If research is to have a chance, either teaching hospitals must set apart research wards or special institutes must be provided for research workers. In this connexion it is worth remembering, as "Junior" points out, that a wealth of material goes to waste in the Poor-law infirmaries of London alone, where there are thousands of patients on whom no observations are made. It would be difficult to sum up the whole subject more tersely and yet more forcibly than "Junior" does when he says: "Choose the workers rather than select their work; give them a fair competency; engage them half time or full time as you will; supply their requests for equipment, material, and assistance. They will do the rest." And all experience shows that if care is taken in selecting the men they may be relied on to do it.

Some Modern Theories Concerning Hysteria.

A PERUSAL of Dr. J. A. ORMEROD'S scholarly Lumleian lectures on Some Modern Theories Concerning Hysteria[1] awakens various lines of thought, a consideration of which may be said to exercise both a stimulating and a sobering influence on the mind. On hysteria, as on the whole question of the psychoneuroses, attention in these days is being focused: the problem of their nature and pathogenesis is being attacked with renewed ardour, and that, too, from widely diverging standpoints. The mere fact of this renewal of investigation is an indication of underlying dissatisfaction with the conflict and rivalry of views of hysteria that have hitherto held the field. Even a definition of hysteria to command general acceptance is not yet forthcoming. Yet it is one of the most ancient of diseases; the student of literature and of history can adduce evidence to prove that its symptoms were known before the dawn of our era; while the student of art can point to mosaics, bronzes, and manuscripts, dating as far back as the fifth and sixth centuries, in which characteristic hysterical features are portrayed. Through the Middle Ages hysteria leaves a trail behind it of ghastly misconceptions and of fatal mistakes in diagnosis.

---

[1] Research in Medicine, its Position and Needs, Morning Post, April 25th, 1914.

[1] THE LANCET, April 25th (p. 1163), May 2nd (p. 1233), and present issue (p. 1299).

And if to-day the sufferer from hysteria is assured of sympathetic handling, can it be alleged with truth that this is a sequel to greater insight into the mystery of the disease? For all our familiarity with it, no one seems to know where it begins and where it ends: there appears to be finality neither in theory nor in symptomatology. Even the classical stigmata on which the student was wont to depend, and thereby to crystallise his conception of the malady, seem to be vanishing. Dr. BABINSKI assures us that he never meets with hemi-anæsthesia now, while he secures a kinematographic record of *la grande crise hystérique* in case it may possibly prove one day of historical interest. If what Dr. ORMEROD calls the palmy days of hysteria at the Salpêtrière are gone for ever, and the hysteria of CHARCOT is obsolete, will the same be said in days to come of the hysteria of FREUD? Listerism has banished hospital gangrene, which survives merely in name, and we are informed by syphilologists that, for instance, rupia and syphilitic cranial osteitis are now rarities. Advances in medical knowledge and consequent improvement in therapeutic technique have definitely altered the manifestations of certain organic diseases. Has, then, hysteria also changed its guise, and are its once familiar features no longer recognisable? We take leave to doubt it. For those whose mental vision is not distorted by what happens to be the vogue of the moment in hysteria it is a pleasure to follow Dr. ORMEROD's able guidance through the maze of hysterical symptoms, and a delight to note his apt modern illustrations of many of these, which the "advanced" theorist would have us discard altogether. Some of the high priests of the latest cult are as intolerant of what is in their eyes heterodoxy as were their mediæval predecessors, whose *flair* for hysteria still amazes us. It is not so much, we suspect, that hysteria has changed, as that the twentieth century Parisian or Viennese, or the Londoner for that matter, has moved away from his forebears in psychical "make-up" and in reaction to his environment. Hysteria is many-sided, and if certain aspects of its symptomatology are for the time being in greater prominence than others, this only means that it has turned its facets in response to the light of research thrown on it from a new direction.

Man has theorised on the nature of hysteria from the days of belief in demoniacal possession to those of what might not unfairly be described as pansexuality. The literature of hysteria is strewn with the wrecks of theories long since forgotten, as are the very names of their authors. Has the disease not been regarded by one as an affection of the ductless glands, and by another as a sort of secondary sexual character? The same fate, we are afraid, will befall other theories that are but of yesterday. Perhaps the reason may be found in the words of old JOHN WYNTER: "The learned physicians, who observed and followed Nature, painted to the Life, in breathing Images, what their Eyes had seen, and their Fingers felt: whereas the Moderns first frame a System or Hypothesis, and then all Appearances must warp to their Whims, and bow the Knee to the Idol their Brain has set up. Hence some by sinking beneath, and others by soaring above the Works of the great Creator, become rather *Ignes fatui*, than true Lights to the Paths of Physic."

Leaving aside certain theories after brief allusion to them, Dr. ORMEROD concentrates attention on those associated with the names of Professor PIERRE JANET and Professor SIGMUND FREUD, and if, on the whole, as we think, it is the theory of the former which appeals to him, Professor FREUD's wonderfully profound investigations into the problem of hysteria are neither underestimated nor unappreciated. At the same time, the lecturer's keen critical spirit leads him to outline various objections to which they are open and which deserve serious and unbiased consideration. Dr. ORMEROD has little patience for the *Sexualitätsschnüffelei* of the exuberant Freudian; if it is ridicule that kills, it is a sense of humour that saves; and could some of the Freudian school show even traces of the latter they would not expose themselves so fatally to the former. Of the literary charms and graces of the lectures we need say no more than that they are wedded to a ripe scholarship; in these essays Dr. ORMEROD has given us of his best.

RÖNTGEN SOCIETY.—The annual general meeting of this society will take place on June 9th, when an exhibition will be held and several lantern demonstrations given. Members desirous of showing new apparatus, negatives, or lantern slides are requested to communicate with the honorary secretary, Dr. Robert Knox, 7, Harley-street, London, W.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general meeting of this association will be held at 11, Chandos-street, Cavendish-square, London, W., on Tuesday, May 19th, at 3.15 P.M., under the presidency of Dr. James Chambers. A paper will be read by Dr. A. Helen Boyle, entitled "Some Observations on Early Nervous and Mental Cases, with Suggestions as to Possible Improvement in our Methods of Dealing with Them." Members will dine afterwards at the Café Monico at 6.45 for 7 P.M. The cost of dinner, exclusive of wine, will be 5*s*. Morning dress will be worn. The annual meeting of the association will take place at Norwich on Tuesday and Wednesday, July 14th and 15th.

Annotations.

"Ne quid nimis."

THE STATE, THE MOTHER, AND THE CHILD.

As we recently stated in a leading article under this heading, the movement towards more definition for the work which the State can undertake on behalf of the mother and the child is receiving an encouraging reception from the Government. But in view of some misinterpretation which has obviously taken place of the intentions of different Government departments, we think it well to point out that the Board of Education have assuredly no intention of undertaking any work which at present devolves upon the sanitary authorities. The Board have for some time been making grants to schools for mothers and similar agencies, and they hope to be in a position to increase the grants in aid to institutions of this nature with a view to developing such work, making it more educational where desirable, and linking it up with the School Medical Service which begins its operations at the time the child enters the school—that is, from 3 to 5 years of age. The promises of the Budget statement may here be borne in mind. In such endeavours the Board will continue as heretofore to encourage and foster coöperation in each area between the sanitary authority and the local education authority and their various officers. Where the medical officer of health is also school medical officer, no difficulties have been found to arise; and where the two offices are held by different persons there is now, as a rule, effective and cordial coöperation. The point is that the Board of Education have never proposed undertaking work in connexion with the prevention of infant mortality, which devolves upon the sanitary authority, nor is there any proposal such as has been suggested in the lay press that the Board should undertake the establishment or control of maternity clinics dealing with the mother as distinct from the child.

DEATH FOLLOWING THE EXTERNAL APPLICATION OF KEROSENE.

PARAFFIN oil is a popular and efficacious agent for the destruction of pediculi. That it must not be used carelessly is shown by the following case reported in the *Australian Medical Journal* of Feb. 7th by Dr. J. K. Adey. A man, aged 73 years, had been in an asylum for three years in consequence of senile dementia. An attendant noticed some vermin in the axillæ, into which he swabbed, but did not rub, kerosene. Some of the liquid ran down the patient's sides into his groins. The kerosene was not washed off and the patient was clothed in a flannel, a shirt, and outer garments, and was seated in a chair in the sun. Seven hours afterwards he was seen by one of the medical officers in a collapsed condition. Large raw surfaces extended from the axillæ to the groins and there was a raw surface in the lumbar region about 4 by 6 inches. Some of the kerosene evidently had run behind his back. The condition was one of superficial burns for which he was at once treated, but he gradually sank and died three days later. It is remarkable that kerosene, which is frequently used as an external application, should have caused such rapid denudation of the skin. The cuticle had peeled off the affected areas. The severity of the result was probably due to the clothes being put on over the kerosene, which prevented free evaporation and the heat of the sun seemed to have aggravated the effect. There seemed no possibility of the kerosene being contaminated as it was drawn directly from the tin supplied by the dealers. A light could not have been set to it as the clothes were not burnt. The necropsy showed that there was no internal lesion and that the patient, considering his age, was in good physical state. Cases in which kerosene has caused reddening of the skin are not infrequent, but a case of death due to its application is so rare as to be of medico-legal importance.

THE STERILISATION OF MILK BY ELECTRICITY.

WITH regard to the interesting investigations which have been carried out for some years in the Thompson Yates laboratories at the University of Liverpool, in connexion with the possibility of sterilising milk by electrical treatment, some important conclusions have now been reached which are published in a report issued last week by Professor J. M. Beattie, the city bacteriologist. It appears that four main lines of investigation were pursued, which were as follows: 1. The effect of uni-directional currents on milk was tried, when it was found that not only did sterilisation not occur under the conditions of the experiments, but that profound changes were produced in the constitution of the milk. 2. The effect of uni-directional and slowly alternating currents with the addition to the milk of minute quantities of salt was next tested with the object of producing electro-chemical sterilisation. It was found that sterilisation could be brought about by this method, and inoculation of the treated milk showed that the bacillus tuberculosis was destroyed. The milk treated in this way was, however, spoiled from the consumer's point of view, on account of profound changes in the milk, and after many attempts to overcome these disadvantages this method was abandoned. 3. Next was tried the effect of static charges of electricity across a moving film of milk, but no appreciable effect was produced on the bacteria. 4. The effect of using a rapidly alternating current was finally tried, and this proved to be the starting point of a system which was ultimately adopted, for even in the early stages of the work with this method it was shown that the bacterial content of the milk could be reduced to a minimum and that the chemical constitution of the milk was apparently unimpaired. A "lethal apparatus" was ultimately designed, and the next points determined were whether the apparatus could be used for large quantities of milk, and whether its efficiency could be maintained over longer periods than those in which it had been ordinarily employed. In the former experiments we may point out that about 2 litres of milk were passed through the lethal tubes in four minutes—that is to say, at the rate of nearly 7 gallons per hour. With, however, a "non-stop" run of from 1 to 1½ hours 9 gallons of milk were treated and the results were quite as satisfactory. It was at this stage that a report was presented to the health committee in which it was stated that "the invariable result" was the "complete destruction of all colon bacilli and bacilli of similar nature with an enormous reduction in the total number of the bacteria of all kinds." It was further reported that when tuberculous milk was used the bacillus of tuberculosis was destroyed. The results of chemical analysis were also satisfactory, and feeding experiments (on kittens) have shown, so far as they have gone, that the nutritive value of the milk is not impaired. A larger scale plant was then installed dealing with upwards of 100 gallons of diluted milk distributed in about 3000 bottles. A system of bacteriological control was instituted, and there appeared to be little doubt that a practical supply of milk free from pathogenic organisms was obtained. On the face of it these experiments would appear to be conclusive, and the results suggest that we are within reach of a process of milk sterilisation which can be applied to practical affairs. It is possible that a remedy for infected milk has been found. The importance of such a finding cannot be denied; but it is, of course, infinitely more desirable that our hands should be strengthened in the matter of a pure milk-supply, not so much in the direction of sterilising infected milk as of cutting off all possible sources of the infection itself. The discovery of a practicable and effectual sterilising process can never justify a relaxation of measures which insist upon a healthy cow and healthy milk. The obvious danger is that if this discovery should attain a wide practical application, the farmer may be encouraged to take the convenient view that preventive measures are not so necessary in view of a remedy having been found. The distribution of tuberculous milk, of course, cannot be justified on any ground. The report awaits confirmatory trials in other places, but we may point out that it contains no particulars as to the cost of the process, though we can hardly imagine that the authors would bring its advantages forward without having reckoned with economical considerations.

DIPHTHERIA AND THE HEART.

IN two directions may the heart evidence the effects upon it of the diphtheria toxin. There may occur sudden heart failure, and short of or preceding this there may arise disturbances of rhythm. Upon both these points recent observations have been made. W. G. MacCallum, in the *American Journal of Medical Sciences* (1914, vol. cxlvii., p. 37) approached, as he has on other occasions other questions of cardio-pathological interest, from the experimental point of view. He instituted a contrivance whereby the dog's heart and the work demanded of it could be controlled at will by variations of aortic pressure. He cut out, in this way, possible general vasomotor disturbing factors. Some hours before the experiment diphtheria toxin was given intravenously, and the animal was sick. It was found that the actual work of the diphtheria heart was at least as good as that of the normal heart, and this even against high pressure. When the diphtheria toxin was given in perfusion fluid, however, a certain feebleness and tendency to irregularity was noted, but the heart continued to beat long after signs of failure in the body of the dying animal, provided the pressure of nutritional fluid was maintained in the coronaries. The results seem to show fairly well that the death which occurs in the height of an attack of diphtheria is not exclusively the result of direct injury to the heart, although that may play some part in the process. On the question of the significance of the arrhythmia which arises in the clinical course of diphtheria, W. E. Hume in *Heart* (1913, vol. xxv.) has added some important facts. He studied in detail four cases, all in children. Three of them were fatal. But the interest lies in the unusually close similarity of the types of arrhythmia, and also in the order in which they successively arose. In some other respects, too, there was similarity of certain features. Thus, three of the cases were from the same school, and presumably infected from the same source; the duration of the illness was almost identical, death occurring on the thirteenth day in two, in the other on the fifteenth. There was also similarity of general clinical signs. The order of arrhythmia observed in three of the cases was this: (1) auricular extrasystoles; (2) nodal rhythm (synchronous auricular and ventricular contractions) occurring on the tenth day; and lastly (3) auricular flutter, a day or two before death in two of the cases; whilst in the third there arose attacks of paroxysmal tachycardia, a closely allied arrhythmia. Such a careful record of events, gained by polygraphic methods, may help to produce a more rational understanding of the significance and also prognostic value of the irregularities so often met with in diphtheria.

WOMEN'S WORK AND THE SHORTAGE OF NURSES.

AN interesting report upon the causes of the shortage of nurses in children's and fever hospitals was recently presented to the Metropolitan Asylums Board by the principal medical officer, Dr. H. E. Cuff. In response to inquiries as to the experience of other institutions, most of the general hospitals in London replied that there was no falling off in the number or social status of candidates for appointment. Most of the Poor-law infirmaries reported an experience of an opposite kind, and the reason appears to be that infirmaries and fever hospitals draw their recruits from the class which takes up nursing as a means of earning a living and has been attracted to fields of work in which they enjoy more personal freedom. The reports from Scottish fever hospitals were as satisfactory as those from English general hospitals; this was attributed to the fact that there were fewer openings for women in Scotland, and that the educational level was higher among them. Dr. Cuff commented upon the falling off in the number of women candidates for the teaching profession and the scarcity of domestic servants. Women, he said, were turning away from fields of work which were peculiarly their own to others where they obtained more freedom or where the outlook appeared less cramped. In spite of the hard work, 1948 candidates competed recently for 80 vacancies at the General Post Office: the number of women employed in the civil service or engaged in various forms of clerical work has risen from 72,048 in 1901 to 152,970 in 1911. There is a serious loss by emigration; in 1908 the number of women emigrants was 97,174: in 1912 it was 168,352. The fever hospitals also suffer, says Dr. Cuff, because trained nurses have now so many fields of employment—in massage and midwifery, as school nurses, health visitors, tuberculosis nurses, and the like—all of which must appear more attractive than life in an institution, especially a fever hospital. Apart from other disadvantages, fever nursing is regarded as a blind alley as far as professional advancement is concerned. Dr. Cuff states that the salaries at present offered by the Metropolitan Asylums Board are well above the average, and that other conditions compare favourably, but the Board must be prepared to do more than is perhaps necessary in the provinces to attract women to its service, especially having regard to the severe competition in London from other hospitals and other forms of employment. Doubtless bearing in mind the difficulty of persuading local authorities to undertake extra expenditure, Dr. Cuff proposes a scale of increased salaries so moderate as to be, in our opinion, of doubtful efficacy. For probationers, to be accepted at 19 instead of 21 years, he has suggested a commencing salary of £20 a year instead of £18 as at present, rising to £22 instead of £20, with proportionate increases in upper grades and special increments of £2 a year after five and ten years' service. Better food and accommodation for nurses and two alternative schemes for granting extra leave are also proposed. The Hospitals Committee adopted the lesser of these schemes and approved the other proposals. On May 2nd the Board, practically without discussion—although in the interval since their first presentation the new arrangements have been subjected to considerable criticism outside—endorsed the action of the Hospitals Committee.

RIGHT-BRAINEDNESS IN RIGHT-HANDED INDIVIDUALS AND THE QUESTION OF "CROSSED APHASIA."

RIVAL theories of aphasia, whichever they be, have never yet succeeded in explaining those anomalous or "negative" cases of which a fair number of instances are now on record. Almost as many "negative" cases exist, which the theory associated with the name of Professor Pierre Marie fails to explain satisfactorily, as anomalous cases left unelucidated by the classical theory, cases to the solution of which Marie's theory was specially directed. Attention has recently, therefore, turned along rather a different line, and some prominence has been given to the possibility of variations in the localisation of the speech centres in different individuals. It is not intended thereby to depreciate the main and well-established facts of localisation, but merely to suggest that in certain otherwise inexplicable cases variations in the site of the speech faculty may be present. This view was tentatively advanced by more than one of the earlier writers on aphasia, but no instance of such variation that has been put on record can compare with one which has recently been worked out by Dr. Kurt Mendel, of Berlin, and published in the *Neurologisches Centralblatt* of Feb. 15th, 1912, and again, with further details, in the number for March 1st, 1914. The patient was a woman, aged 42, who was certainly right-handed, and in none of whose relatives had left-handedness ever been remarked. As the result of an embolus from cardiac disease she became paralysed on the whole of the left side, and had complete motor aphasia. The lesion was eventually found to be an embolic softening of the right inferior frontal convolution, the right island of Reil, and the right superior temporal convolution. Not content with a macroscopical examination merely, Dr. Mendel has made a microscopical investigation of both hemispheres, and is able to state that the lesion is as above mentioned; the left hemisphere is intact, and the pyramidal paths are normally crossed in the lower part of the medulla oblongata. The case therefore stands on record as one in which the motor speech centres are definitely placed in the right hemisphere in a right-handed woman. But as there was no trace of sensory aphasia in this case and no agraphia, the sensory speech centres must be localised in the left hemisphere, seeing that the right superior temporal gyrus was destroyed. In other words, the case is one of "crossed aphasia," one in which there is a proven dissociation of the motor and sensory speech centres. The importance of the case will be obvious to all who are interested in the problems of cerebral localisation. It is paralleled to some extent by another recent case recorded by Dr. E. Long,[1] in which the motor speech centres were proved to be on the right side, and the sensory speech centres on the left, in a left-handed patient. These and other cases suggest that differing degrees of right- and left-handedness exist, and that corresponding to the intermediate stages between absolute right-handedness and absolute left-handedness are possibly analogous variations in the complete or incomplete representation of the speech centres in one or other hemisphere. If this view is based on evidence which is not as yet very complete, at the least it has much to recommend it, and further investigations calculated to throw light on this important question will be awaited with interest.

ANTITUBERCULOUS VACCINATION.

IN 1913 Professor Maragliano published the latest results of his studies as to immunisation against tubercle by means of the antituberculous vaccine made by him at his institute at Genoa. Since then Dr. Eugenio Curti has performed 586 vaccinations of this kind, and gives his experiences of the method in a paper in the *Gazzetta degli Ospedali* of April 9th. Of the 586 persons vaccinated, about 5 per cent. gave no reaction of any sort either local or general, and these were for the most part robust individuals with good family history. The absence of reaction was attributable to special organic resistance, and not to any error in technique. In 80 per cent. there was sometimes, and after a few hours, slight aching in the arm, accompanied by tingling, and at the site of inoculation first a redness appeared, followed by a pustule which lasted some days, this being followed in its turn by a yellowish scab, which after falling left a hard nodule, and afterwards a dull red stain. These manifestations were accompanied by some local itching and a rise of temperature rarely exceeding 37·5° C., which was not always noticed by the patients, who merely complained of lassitude. This subfebrile state began about 24 hours after the inoculation when the pustule formed and lasted a couple of days. This took place in perfectly normal individuals. In about 15 per cent. there were pustules which assumed the dimensions of a halfpenny, and were accompanied with swollen axillary glands and a febrile reaction of 39°. These patients, however, did not complain of feeling ill, and were not prevented from following their occupation. The local manifestations lasted for ten days also in these cases. A further investigation into the condition and history of such patients showed that they were persons with a bad family history, or who lived with tuberculous people, or had some form of strumous manifestation, or were in such a poor state of health as to warrant the suspicion of a special predisposition to tubercle. When persons with advanced tubercle were vaccinated in this way a strongly marked reaction occurred. It seems, therefore, practically certain that antituberculous vaccination is absolutely innocuous and is useful; moreover, in that it affords, by the intensity of the local manifestations, a criterion by which the greater or less resistance of the patient to tubercle may be judged. What will be the advantages derived from Maragliano's vaccination in the future remains to be seen. Certainly if it were the means of saving not more than 10 per cent. of those predestined to tuberculosis, it would be a victory to be proud of.

---

BLINDNESS, SMALL-POX, AND VACCINATION.

THE admirable work done by the United States in the Philippines in the practical stamping out of small-pox, though less spectacular than the elimination of yellow fever from Havana and the Panama Canal Zone, is nevertheless of the utmost value, not only for its immediate results, but in consequence of its demonstration of the efficacy of vaccination when thoroughly and radically enforced. It is well known that before the occupation of the Philippines by the United States small-pox was always endemic; and its exacerbations were frequent and severe. So far back as 1899 Dr. Llewellys F. Barker stated that when the American army first went to Manila it had a large mortality from small-pox, which was as common among the natives as scarlet fever or measles in America, a large proportion of the faces encountered being pitted. Wholesale vaccination by Dr. Bourns with the aid of 18 Filipino physicians had, however, entirely wiped the disease out. It has been for years rarely in evidence in the reports of the principal zymotic diseases in foreign places, published weekly in the United States Public Health Reports; the Report for April 3rd shows for the third quarter of 1913 only 15 cases, while the Report for the fourth quarter shows no cases and no deaths. This valuable official publication for March 27th, 1914, contains an authoritative account of a most interesting investigation regarding the prevalence and causes of blindness in Cebu. Twenty-three towns were visited, of which 12 reported blindness. In all 145 cases were examined, and the chief cause was found to be small-pox, 48 cases. Most of these small-pox cases had been blind for many years, only 3 having occurred in the past five years. The Report adds: "Since the Americans have begun the systematic and compulsory vaccination of all people small-pox is no longer a cause of blindness."

UTERINE ENDOSCOPY.

To the already formidable list of instruments for peering into the recesses of the human body Dr. Alfred Heineberg, a Philadelphia gynæcologist, proposes to add yet another. His preliminary announcement, in the April number of *Surgery, Gynæcology, and Obstetrics*, begins with a recitation of the means hitherto employed for the diagnosis of intra-uterine disease: bimanual palpation of the uterus as a whole, the uterine probe, digital exploration of the uterine cavity, and microscopic examination of curettings from the uterine mucosa. As he points out, the method of curettage, to which most importance is attached in the diagnosis of uterine cancer, yields valuable results, but often disappoints or misleads just in those cases where its help would have been most desirable. He has therefore designed an endoscope for visual examination of the interior of the uterus, consisting of an endoscopic tube, irrigating attachment, obturator, and lighting attachment. He has used it in about 20 cases, in all of which it was proposed to perform dilatation with curettement. By this means it is possible to see the lining membrane of the uterine body as of a velvety appearance and dark red colour. The slightest injury provokes bleeding. The cervical mucosa is pink or yellow according to its vascularity, and the arborising lines can be readily detected. He describes two cases in which facts of diagnostic value were brought to light by this method. In one a patient suspected of malignant disease was found to be suffering from villous endometritis. The other was a case of incomplete abortion; here uteroscopy discovered a piece of fœtal envelope adhering to the fundus, whence it was readily detached with small placental forceps. Hitherto Dr. Heineberg has carried out this procedure under general anæsthesia, but he thinks it will be possible to use local anæsthetics only in certain selected cases. Careful asepsis is, of course, as essential as in any intra-uterine procedure. Acute anteflexions, which might constitute a bar to inspection of the uterine cavity, may be overcome, he thinks, by careful dilatation of the uterine canal with bougies. Profuse bleeding is an absolute obstacle to the application of this method, a circumstance which, if it prove insurmountable, will greatly restrict the value of uterine endoscopy. Moreover, as Dr. Heineberg observes, incautious use of the instrument is capable of inflicting serious injury, especially in cases of acute infection of the genital tract; and in pregnant patients it would, of course, be absolutely inadmissible. It remains to be seen, therefore, whether a method which is subject to so many restrictions will yield information of sufficient importance to justify its application on any considerable scale. Whether or not, it is an interesting venture. The progress and manifold applications of the endoscopic plan of diagnosis during the past 50 years constitute a remarkable illustration of the psychological fact embodied in the popular saying, "Seeing is believing."

PATHOLOGICAL ANTAGONISM IN RELATION TO DIABETES.

IT is a clinical fact, to which, perhaps, too little attention has been paid, that one disease may appear to antagonise another. In this relation erysipelas may afford a striking example, an attack cutting short other conditions. The explanation of these facts is not at present known. There are other ways, too, besides that of one disease by its incidence obliterating the effects of another which demonstrate this antagonism. Thus one disease may replace another when the former is intermittent in incidence; or direct medical intervention, such as a surgical operation, may check an old-standing pre-existing disease, against which such intervention was not primarily directed. H. S. Stark in the *Medical Record* (1914, vol. lxxxv., p. 645) records some interesting observations in relation to diabetes. He recognises three groups in which pathological antagonism can be noted. (*a*) Where an intercurrent symptom checks the glycosuria. In two cases of diabetes an attack of urticaria stopped the excretion of sugar. More interesting than these, perhaps, was a case of diabetes in which the patient contracted syphilis. So long as the Wassermann reaction was positive the glycosuria persisted; when the negative reaction occurred there was cessation of the excretion of sugar. A second case showed similar findings. (*b*) Where an intercurrent disease checks the glycosuria. In this relation he has noted the cessation of the sugar following the advent of pneumonia and also of typhoid fever. (*c*) Following operation, cessation of the sugar excretion. He comments, too, upon the supposed intimate connexion between pulmonary tuberculosis and diabetes. It is held that the diabetic is especially prone to succumb to phthisis. This view requires modification, but it is, conversely, a clinical finding that pulmonary tuberculosis itself appears to lessen the susceptibility to diabetes. Possibly in this connexion there is to be seen a similar pathological antagonism, the onset of tuberculosis in diabetes being explainable solely by the lowered vitality of the diabetic and not by any especial susceptibility which diabetes in itself confers upon the patient. Observations of this general character are favoured by long acquaintance with the patient. Such are not easy to make in general hospital work, and it is probable that additions to our knowledge would be more easily made by the general practitioner with his long individual familiarity with his patients rather than by the hospital physician.

NEURALGIA OF VENOUS ORIGIN.

Professor L. Edinger, of the Neurological Institute in Frankfort, deals with a little recognised, if not infrequent, condition in a recent number of the *Berliner Klinische Wochenschrift* (No. 11, 1914). Many differing morbid changes may produce neuralgic pains in the lower extremities, often grouped indiscriminately as sciatica, and the better acquainted the physician becomes with these the less likely is he, in practice, to meet with cases of neuralgia pure and simple, for the obvious reason that the underlying pathological state does not escape him. Insufficient examination is, however, only too prone to lead to failure in treatment if once so comprehensive a diagnosis as sciatica is made; content with that, the spirit of investigation seems to go to sleep. Professor Edinger describes several cases that have recently come under his notice with a ready-made diagnosis either of sciatica or of crural neuralgia; not the diagnosis, but the failure to effect a cure led to their being sent to him. Yet until the etiology was recognised therapeutic endeavour was necessarily fruitless. One of these cases was that of a healthy man, aged 22, who received a kick on the left shin just below the knee when playing football; unfortunately an iron firescreen fell on exactly the same spot not long after, with the result that, following on a severe local hæmorrhagic effusion, acute pains developed in the limb, on which eight weeks' rest in bed and numerous forms of treatment had little or no effect. For no less than three years the pains continued in spite of every attempt to relieve them. The patient was able to cycle for some distance, but the pains came on if he had to climb an ascent. He was able to ride on horseback, though pressing his knee against the horse's side induced the pain. He could walk upstairs quite well and always felt the pains worse if he stood for any time. The contradictory nature of the complaint, as it appeared to some physicians, had led to a diagnosis of hysteria. There were no signs of organic nervous disease. Professor Edinger noticed on examining the patient that some superficial veins over the calf were dilated, and the idea of a varicose condition of the veins of some nerve trunk, or in the neighbourhood of a nerve trunk, came to him. The simple application of an elastic bandage effected a speedy and permanent recovery. Another case was that of a medical man, aged 56, who, after a chill, developed so-called sciatica in the left leg. Yet the pains were worse on standing or sitting, while walking always relieved them. They were localised mainly on the back of the knee, but were felt also in the buttock; their frequent appearance at the head of the fibula led to a diagnosis of peroneal neuralgia, but this the patient himself would not accept, although it was clear that they began in that region. The whole leg below the knee ached, while pressure on the sciatic nerve at the sciatic notch was painful. The pains were always alleviated by walking upstairs and aggravated by standing or walking slowly. Every conceivable treatment for sciatica was at one or other time utilised, but without result. The patient, however, was one day examined in a standing and not a recumbent attitude, when small varicose veins were noted on the back of the knee and a diagnosis of deep varicose veins made. Treatment along suitable lines at once led to a satisfactory cure. The value of examination in a standing position is emphasised in all the cases here published by Professor Edinger. No doubt pain in association with varicose veins is familiar enough to the clinician, but the possibility of a deep varix, either in or near a nerve trunk in ambiguous cases of crural neuralgia, is well worth keeping in view. Researches by Reinhardt and Spalteholz, using the injection method, show that in its upper part the inferior gluteal vein lies directly on the sciatic nerve; from it the descending vena ischiadica accompanies the nerve, either lying superficially or actually embedded in the nerve. At intervals along the nerve junction is effected with small neighbouring veins, and at the knee there are anastomoses with the small saphenous and the popliteal. Varices are most apt to occur where anastomoses are found. There are in addition, however, much smaller veins running in the nerve trunk itself, a varicose condition of which could not be detected by clinical examination. Professor Edinger's paper serves a useful purpose in directing attention to this aspect of neuralgia of the lower extremities.

CONTROL OF GLANDERS.

THOUGH the number of deaths that are due to glanders is small, yet the almost invariably fatal nature of the malady makes it one which requires the most careful attention from public health authorities, while its incidence on the horse population is a cause of much pecuniary loss to owners and of suffering to the animals. It may, therefore, not be amiss to consider the methods adopted in other countries for the control of this disease. The February Bulletin of the Department of Health of the City of New York is devoted to this subject and gives an account of the methods of diagnosis there employed. Human deaths from glanders in New York average about 3 a year, the highest number recently being 5 in 1912, and the lowest 1 in the following year. When a case of glanders is recognised in a stable, blood is taken from all the other horses and examined by the complement-fixation test. This is analogous to the Wassermann reaction as used in the diagnosis of syphilis, the antigen being prepared from pure cultures of bacillus mallei. If a positive reaction is obtained, the animal from which the blood was taken is then examined further by means of the conjunctival test, analogous to Calmette's reaction in tuberculous human beings, four or five drops of undiluted mallein being dropped into the conjunctival sac. In infected horses a reaction commences within six or eight hours and may last from 36 to 48 hours, the eye becoming inflamed and giving rise to a purulent secretion. These two tests applied together are held to give a certain diagnosis, and animals which react to both are destroyed on the strength of them. Other tests for the disease are the intradermal method of injecting mallein, by which a localised swelling in the skin is produced in infected horses, and the agglutination reaction, in which a positive result in a dilution of 1:1000 or over is held to indicate the existence of glanders. The original method of subcutaneous injection of mallein does not seem to be now so often employed, but with care it is also capable of giving reliable results, a rise of temperature of not less than 2·5° F. being considered positive evidence, the temperature of the horse's body rising to at least 103°. Horses which have been exposed to infection, but which give a negative reaction to the tests used, should be examined again after 15 days' interval. It seems that the agglutinins are the earliest antibodies to appear in the course of the infection, being present within the first four or five days. The specific amboceptors upon which the complement-fixation test depends are likely to appear within a week or ten days after infection, while the conjunctival reaction cannot be relied upon to appear before the lapse of three weeks. It must further be remembered that an injection of mallein for diagnostic purposes may itself give rise to the formation of antibodies, which may remain for six or eight weeks, while a vaccine of glanders bacilli may cause the continued presence of these bodies for a period of three months or more.

A PROVINCIAL SYPHILIS DISPENSARY.

THE account given by Dr. E. Malvoz, in the April number of the *Revue d'Hygiène*, of the organisation and work of the Ehrlich dispensary in Liége will interest many English readers, particularly those who have insisted that action by public authorities in this country to diminish syphilis can be successful without requiring compulsory notification of the disease. The Liége dispensary serves the city and province of that name. It is situated in a quiet corner of the town, on the banks of the Meuse, and contains laboratories at which Wassermann tests and other pathological work are done and injections are prepared, as well as the ordinary equipment of a dispensary. The staff comprises an administrative officer, four physicians, a bacteriologist, and a pharmacist, and the consultation days for men include Sundays at 9 A.M. and Saturdays at 8 P.M. From June, 1912, to December, 1913, 833 persons have been treated at weekly attendances, of whom 479 came from communes in the province outside the city. The great majority have come for treatment in the primary or secondary stage, mainly at the instance of the local practitioners, whose coöperation has been very assiduously sought by the management of the dispensary. The dispensary does not undertake the treatment of locomotor ataxy, general paralysis, or other "parasyphilitic" affections which are referred to other establishments. The salvarsan injections hitherto have been made without any untoward results, and in all cases the patient has been able to return home after the injection. Little difficulty seems to have been found in securing that the patients continue to attend for after-observation, and it is made a strict condition that they will keep in necessary communication with the dispensary for some years, so that the results of the treatment can be properly ascertained. The medical staff, according to the system, at no time know of any patient except under a number given to him on his application. Dr. Malvoz states that the patients are greatly struck with the precautions taken in this respect, and that it is one of the causes of the success of the undertaking. Practically the whole of the expense is defrayed jointly by subventions from the municipality and from the province of Liége. Diagnostic tests are free to everyone on making an application endorsed by a medical practitioner; the treatment so far has been limited to those whom there is reasonable ground to suppose would be unable to afford the cost of a "cure stérilisante." Special arrangements are made for pregnant women. The circulars as to the aim and functions of the dispensary, issued under municipal authority to medical men, local administrative bodies, and the public, are admirably drawn up with a view to encourage application at the earliest time after diagnosis, and the committee of the dispensary has issued a strong appeal to the various insurance societies to reverse their usual practice of withholding benefit from members attacked by syphilis. The progress already made seems sufficiently substantial to make this system of municipal action worthy of the attention of the English Royal Commission from the point of view of its applicability to English local public health administration.

THE annual dinner in London of the Indian Medical Service will be held at the Hotel Cecil on Monday, June 8th, at 7.45 P.M. The Edinburgh dinner of the Indian Medical Service will be held on Friday, May 29th, in the Caledonian United Service Club, Sir Alexander Christison, Bart., in the chair. Application for cards for the Edinburgh dinner should be made to Colonel Arnott, 8, Rothesay-place, Edinburgh.

THE Medical Society of London will hold a conversazione at 11, Chandos-street, Cavendish-square, on Monday evening, May 18th, at 8.30. The annual oration will be delivered by Mr. Robert Jones at 9 P.M. on the Surgical Aspect of Poliomyelitis. During the evening the society's Fothergillian medal will be presented to Professor J. G. Adami, F.R.S., of Montreal.

THE Ingleby lectures for 1914 will be delivered on Thursdays, May 21st and 28th, at 4 P.M. in the Medical Lecture Theatre of the University of Birmingham, by Dr. T. Stacey Wilson, physician to the Birmingham General Hospital, on the subject of Neurasthenia: Its Causes and Cure.

INVALID CHILDREN'S AID ASSOCIATION.—The annual meeting of this association will be held at Seaford House, 37, Belgrave-square, S.W., on May 19th, at 3 P.M. Field-Marshal Lord Methuen will preside, and the Bishop of London and Sir Thomas Barlow will be among the speakers. Application for tickets may be made to the secretary, 69, Denison House, Vauxhall Bridge-road, S.W.

THE INTERNATIONAL SURGICAL ASSOCIATION.

(FROM OUR OWN CORRESPONDENT.)

(Continued from p. 1271.)

THE Congress resumed its sittings, under the presidency of Dr. A. Depage, at the Hotel Astor, New York City, on Tuesday, April 14th. The morning and afternoon sessions were devoted to the reading and discussion of papers on gastric and duodenal ulcers. Wednesday's sessions were given up to papers and discussions on grafts and transplantations, while on Thursday the discussion on the surgery of gastric and duodenal ulcer was concluded.

Gastric and Duodenal Ulcers.

Dr. F. de QUERVAIN (Basle) was on the programme for the first paper, dealing with the diagnosis of gastric and duodenal ulcers. As he was not present his paper was taken as read. His communication dealt in particular with clinical and radiological diagnosis of these conditions and the problems concerned therewith. He affirmed that apart from certain well-established facts there remain a great number of open and controversial questions, and he confined himself to those problems in diagnosis which are still uncertain, in the hope that the Congress would throw some light upon them. The debatable questions selected by him were the following:—1. What is the frequency of spasm in the superficial ulcer of the lesser curvature? 2. Under what conditions does this spasm occur in the absence of any ulcer? 3. What are the surest and most practical distinguishing signs between pyloric spasm and pyloric stenosis in the beginning? 4. What is the diagnostical meaning of the persistent repletion of the duodenal bulb ("gastric bonnet")? 5. What is the symptomatological value of the duodenal movement of the stomach? 6. What differentiation is there between duodenal ulcers encroaching upon the pylorus, true pyloric ulcers, and duodenal ulcers of low situation, from the point of view of their action on the pyloric reflex and on the gastric chemistry? 7. What are the surest radiological signs of adhesions in connexion with the stomach and duodenum?

The next paper was a joint contribution by Dr. H. HARTMANN and Dr. P. LECÈNE (Paris), which was read by Dr. Hartmann. The authors expressed the opinion that while duodenal ulcer was certainly more frequent, its frequency had been exaggerated, and in France, at the very least, they had noticed on an average one ulcer of the duodenum for eight or ten ulcers of the stomach. Moreover, they thought that the clinical criteria and the anatomical characteristics, the situation and disposition of the pyloric vein, were far from being beyond criticism. In their opinion the symptomatology described by Moynihan was simply that of pyloric spasm, while as for the pyloric vein it was very unreliable as regards situation and disposition. At the base of callous ulcers of the stomach, which were situated especially on the lesser curvature, were frequently to be found evidences of neuritis in the small nerve ganglions lying in the substance of the sclerosed muscular coats. These changes might account for the persistent pains which were often the predominant symptom of such ulcers. With regard to surgical treatment the authors preferred posterior gastroenterostomy performed on the pyloric antrum itself.

Dr. W. J. MAYO (Rochester, Minnesota) read a paper on

Chronic Ulcers of the Stomach and Duodenum.

He pointed out that the first case of pyloric obstruction was operated upon in St. Mary's Hospital, Rochester, in 1895, a Heinicke-Mikulicz pyloroplasty being performed. The second operation was a gastro-jejunostomy with the Murphy button. From 1900 to 1906 it was recognised that obstruction was a terminal condition, and studies were undertaken with a view to the early termination of the malady. The suture took the place of the Murphy button and the posterior method of gastro-jejunostomy replaced the anterior method. From 1906 to 1914 the relation of the clinical symptoms to the lesion came to be better understood, the Roentgen ray took the first place in the diagnosis of these lesions, the value of the purely laboratory examination of gastric contents was found to have been overestimated, and the necessity for the excision of gastric ulcers, because of the menace of cancer, was recognised. Dr. Mayo laid stress on the point that in differentiating between an ulcer in the pyloric end of the stomach and one in the first portion of the duodenum the situation of the pyloric vein is the determining factor. He explained that the terminal three-fourths of an inch of the pyloric end of the stomach was not often involved in ulcer. The more common seat of gastric ulcer was along the lesser curvature, often saddle-shaped. The ulcer was more often on the posterior than the anterior wall, but whether situated anteriorly or posteriorly a superficial ulcer at the point of contact often appeared on the opposite wall—the "contact" ulcer. Multiple ulcers were not frequently found at operation, contrary to the early views based on clinical observations and post-mortem findings in deaths due to acute ulcerative processes in the stomach. These processes were usually gastro-toxic in origin and not often the source of chronic ulcer. The character of ulcers of the duodenum differed in many respects from that of ulcers of the stomach. They were usually to be found in the upper two inches of the duodenum and more often in the antero-superior wall. When found on the posterior wall they were usually of the same character as when found in the stomach. As a rule, the duodenal ulcer had its origin below the pylorus, but when it extended towards the stomach it usually stopped short at the pylorus, which it might undermine. In exploring for ulcers of this description there was occasionally a difficulty in discovering the posterior ulcer because it was concealed under the projecting pyloric ring. The mucous membrane of the upper duodenum was thin and glandular, and ulcers confined to the anterior wall, if they assumed eventually the crater-like character of the gastric ulcer, would develop into a localised mass over the site of the ulcer. Often, however, no crater was found in the mucous membrane in duodenal ulcer, but rather a discoloured, motheaten-looking patch, in the centre of which might be a dimple-like ulcer and outside this a typical induration. This variation from the ordinary type of ulcer probably explained why duodenal ulcers had so often been overlooked at necropsy. Dr. Mayo thought that permanent healing of chronic ulcers of the stomach and duodenum by non-operative means must be of rather infrequent occurence. Gastro-jejunostomy was the most generally useful operation for gastric ulcer, and had a wide field of application. Especially was this true when there was obstruction in the vicinity of the pylorus. While posterior gastro-jejunostomy was the operation of choice, in certain cases adhesions might prevent its use. In these cases the anterior operation had given good results. Dr. Mayo insisted that because of the menace of cancer all ulcers of the stomach, without regard to their situation, should be excised if possible. Local excision of the ulcer without gastro-jejunostomy had sometimes failed to effect a cure. Therefore, as a rule, gastro-jejunostomy should be done in addition to excision. Gastro-jejunostomy was a most satisfactory operation in all those cases of ulcer of the duodenum in which there was actual or potential obstruction. Moynihan had been followed in enfolding the ulcer with fine silk and placing one or two sutures in such a manner as to block the pylorus to prevent food from entering the ulcer and during the healing period. This blockage by suture could not be expected to be permanent, but in connexion with the permanent obstruction produced by healing of the ulcer it usually answered the purpose. If there were neither actual nor potential obstruction, this blockage should be accomplished by more efficient means. Referring to the results of operative procedures, Dr. Mayo thought that at least 95 per cent. of those with gastric ulcer would be cured or greatly relieved by operation. The operative mortality in the gastric ulcers at St. Mary's Hospital, Rochester, counting all cases dying in the hospital without regard to the length of time after the operation or to the cause of death, was 3·8 per cent. The results in duodenal ulcer were extraordinarily good, 98 per cent. of the patients either having been cured or greatly relieved by the operation.

Dr. E. PAYR (Leipsic) read a paper on

Ulcers of the Stomach and Duodenum.

He maintained that with regard to etiology and pathogeny there were two principal theories: (*a*) that of a gastric or duodenal vascular lesion (thrombosis, embolism, sclerosis);

and (*b*) nervous origin by vaso-motor spasm leading to a localised ischæmia of the mucosa; the cause of this spasm will be a disturbance of the sympathetic nervous system. Neither of these theories was sufficient to explain every case, and many points in gastro-duodenal biological chemistry were still unexplained. Some mechanical causes operated in the localisation and the form of the ulcers. Bacterio-toxic lesions also played a certain part. With regard to variety, Dr. Payr distinguished two types of duodenal ulcer according as its position was on the anterior or posterior wall. The first presented more a tendency to perforation, the second to hæmorrhage. Between the ulcer of the duodenum and that of the stomach there existed very appreciable anatomical and chemical differences. With regard to degeneracy, Dr. Payr said that cases of malignant transformation of ulcers undoubtedly occurred, and such "cancerised" ulcers could be readily distinguished from ulcerating cancers. But it was often difficult to differentiate these two types from simple callous ulcers, especially when it was a question of cancers possessing numerous fibrous tissues such as Thomson's fibroids. Ulcer and cancer might also coincide in the stomach. Ulcer of the duodenum showed very rarely a carcinomatous degeneracy. With regard to technique, the callous ulcer of the stomach should be resected whenever the general condition of the patient permitted, especially when it was a question of small ulcers situated at a distance from the pylorus at the lesser curvature and on the posterior surface. In all other cases posterior gastro-enterostomy was the operation of choice. The excision of gastric ulcers, unless accompanied by gastro-enterostomy, generally gave unsatisfactory results on account of the persistent pylorospasm. For duodenal ulcer the best intervention consisted of a gastro-enterostomy combined with a unilateral pyloric exclusion after von Eiselsberg's method. If this operation was not feasible the best way was to shorten the pylorus by means of an aponeurotic band or a suspensory ligament. It was necessary to bury the band under a sero-serous continuous suture. The exclusion of the pylorus might be combined with a suspension of the stomach. Von Eiselsberg's technique alone gave certain results. In ulcers of the lesser curvature and those of the posterior surface total segmentary resection with axial suture of the stumps gave the best results. Gastro-enterostomy for simple or callous ulcers necessitated a consecutive treatment of atropine and alkalies for at least a year. In cicatricial stenosis of the pylorus gastro-enterostomy gave excellent results; but with active ulcers, especially when distant from the pylorus, the results were less reliable. Only in 50 to 66 per cent. of these cases was success achieved. The mortality in resection of ulcers, especially by the total segmentary method of Riedel, was 10 per cent. or less, but it remained higher than that of gastro-enterostomy. The clinical results of resection were good.

(*To be concluded.*)

MEDICINE AND THE LAW.

The Workmen's Compensation Act.

His honour Judge Mulligan, K.C., recently delivered judgment at Norwich declining to review an award of 5s. a week made to a labourer named Page in respect of injuries received in the service of his deceased employer, Mr. H. Hammond. The ground for the application was that the workman's present incapacity was not due to the accident. It was admitted that Page was unable to earn full wages, that since the date of the accident general paralysis of the insane had supervened, and that at an earlier date when he could have done light work he did not try to get it. His honour in giving his decision based it on Plumb *v.* Dawson, a case decided in December, 1913, and upon findings of fact which he stated thus:—

1. A constitutional predisposition rendered Page more prone to succumb to the malady than a man of normal condition.

2. The accident preyed on his mind and set up over-excitement of the brain, which either formed part or was an offspring of the original injury.

3. The worry worked on the over-susceptible brain and was the exciting cause of the malady.

4. The malady had destroyed conscious volition and thereby incapacitated the man for work, for he was bereft of will-power by the accident.

5. Had it not been for the enforced illness consequent on the accident and for the attendant privations and worries, multiplied as they were by the unjust stoppage of all compensation in January, 1913, Page would now in all probability be doing his usual work.

6. The incapacity of Page for work was one of "the entire results causally connected with the injury." (Ball *v.* Hunt, 1, W.C.R. 267.) The chain of causation was complete.

Wall v. Gretor.

Mr. Justice Lush, sitting without a jury, was occupied recently for some time with the trial of an action brought by Mr. V. F. Wall against Mr. W. Gretor to recover £141 19s. for medical attendance. According to the plaintiff's case he attended the defendant, who was addicted to morphia, from January to October, 1913, and ceased to do so on account of offensive observations made to him by the defendant in the presence of the defendant's servant with regard to his (the plaintiff's) personal appearance and clothing. He charged a guinea for ordinary visits and 2 guineas for visits of more than 30 or 40 minutes and for visits after dinner. The defence was that the charges were excessive. Evidence was given on both sides, alleging and denying a verbal arrangement as to the fees to be charged. The defendant himself was not present at the trial, and his evidence had not been taken on commission. Mr. Justice Lush, in giving judgment, observed that the defendant was a gentleman of considerable means who suffered from the habit of taking morphia in large doses, and that medical men undertaking such cases would probably make arrangements beforehand to charge special fees. It was necessary for the medical attendant to acquire, if possible, influence over his patient. The plaintiff, he found, had made the bargain referred to above, and there was no reason for abating the sums charged. No charge in some instances had been made where it would have been reasonable to make one. Deducting 2 guineas for an occasion when the plaintiff and his wife had dined with the patient, his lordship gave judgment with costs for the amount claimed, less £40 paid into court.

The Privilege of Medical Witnesses.

The question of a medical man's duty with regard to his patients[1] and of his *right to claim* privilege in the witness-box was again raised in a county court, and in a claim under the Workmen's Compensation Act, in an arbitration before his honour Judge Longstaffe, at Dewsbury. The claimant for compensation had been burnt in an explosion of gas when lighting a lamp in the early morning, and it was alleged on the part of the employers that on Dec. 6th, on which day she went to her home, she had been pronounced by a medical man to be likely to recover in two days, her claim being for compensation up to Jan. 5th. The employer's solicitor accordingly proposed to put Mr. G. Patterson, medical attendant under the Insurance Act to the claimant, in the box, to which her advocate objected. The judge ruled that the matter lay between Dr. Patterson and his own conscience, and he was sworn. On his being asked a question as to the condition of his patient when under his care, he was told by Judge Longstaffe that he was not obliged to answer it, but he said that he saw no reason why he should not do so. When his answer was heard it was found to be to the effect that on Dec. 6th there was still injury from the burn, but that he thought it would be better in a few days. From the condition of the girl's arm when he saw it he thought she might be incapacitated till Jan. 5th. This was the date on which according to the claimant's own case her incapacity ceased, and judgment was given for her for the amount claimed. It will be seen, therefore, that the evidence of the medical attendant was in favour of his patient's case, and that the objection raised on her behalf to his giving evidence was not necessary. He undoubtedly exercised rightly his discretion, but a different problem would have arisen if the result of his observation had been that the claimant was asking for compensation to which she was not entitled. If this had been so, his evidence, if given, would have been detrimental to his patient's case. As to this some will say that he would then have done rightly in declining to answer, others that he would have been right if he had spoken out and assisted the court to arrive at a just decision. It is in fact as well as in law, as the judge pointed out, a matter of conscience. Probably in practice if a medical man is not called on behalf of his patient and declines to answer questions when asked by the other side who have put him in the witness-box, an inference hostile to his patient is usually to be drawn, so that the result is not likely to be very different from what it would be if he spoke out. In the particular case described above it is to be supposed that neither side knew what the medical man was prepared to say, and it may even be suggested that if they had known the case might not have come before the judge.

[1] THE LANCET, April 4th, p. 978.

Henry Delvine, "Cancer Expert."

At the Central Criminal Court Henry Delvine, whose exploits as a "cancer expert" have attained for him notoriety through numerous prosecutions having been initiated against him in the country as well as in London, was sentenced to 15 months' imprisonment with hard labour. We need not tell the story of the case in detail, as the press has given full publicity to it. The indictment charged him with obtaining money by false pretences and he pleaded guilty to it. One of the methods frequently adopted by Delvine was to administer a supposed treatment and then, after personally examining the patient either alone or with only a person employed by himself present, to produce a piece of animal offal purchased from a butcher which he would display as "a removed cancer." It may be mentioned as showing the hold which the prisoner acquired over the public that he was recently charged at Downham Market with a criminal assault upon a married woman alleged to have been made under the pretext of an examination, and that when the magistrates dismissed the charge Delvine was carried shoulder high through the town. Before he was sentenced he was described by counsel for the prosecution as being an illiterate person, who had been a soldier, a county court bailiff, and a labourer.

SOCIAL WELFARE ASSOCIATION.—The annual meeting of this association will be held at the Mansion House on Monday, May 18th, at 3 P.M. The Lord Mayor, as President of the association, will preside.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on April 30th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College:—Richard Robins Armstrong, M.B. Cantab., L.R.C.P.; George Ernest Beaumont, M.B. Oxon., L.R.C.P.; Harold Black, M.B. Belf. (Birmingham); Arthur Neville Cox, M.D. Lond. (Brighton); Trevor Braby Heaton, M.B. Oxon.; Geoffrey Hoffmann, M.B. Cantab., L.R.C.P.; William James O'Donovan, M.D. Lond., L.R.C.P.; Frederick Paine, L.R.C.P. (Woodford Bridge, Essex); John George Porter Phillips, M.D. Lond., L.R.C.P.; Arthur John Scott Pinchin, M.D. Lond., L.R.C.P.; Thomas Henry Gostwyck Shore, M.B. Cantab., L.R.C.P.; Atul Krishna Sinha, M.B. Cal., L.R.C.P.; and Kenneth Douglas Wilkinson, M.D. Birm. (Birmingham).

Licences to practise physic were granted to 105 gentlemen who had passed the required examinations.

The following Members were elected Fellows of the College:—Cuthbert Henry Jones Lockyer, M.D. Lond.; William Mitchell Stevens, M.D. Lond. (Cardiff); Arthur Stanley Barnes, M.D. Lond. (Birmingham); James George Taylor, M.D. Cantab. (Chester); Dudley William Carmalt-Jones, M.D. Oxon; Samuel Alexander Kinnier Wilson, M.D. Edin.; Hector Charles Cameron, M.D. Cantab.; John Foster Gaskell, M.D. Cantab.; Gordon Morgan Holmes, M.D. Dub.; Robert McCarrison, M.D. R.U.I. (Bombay); Frederick Gowland Hopkins, M.B., D.Sc. Lond., F.R.S. (Cambridge); and Sir Alfred Henry Keogh, M.D. Q.U.I.

Sir William Boog Leishman, M.B. Glasg., F.R.S., was also elected a Fellow under By-law LXXI (b).

The following communication was received: From the Secretary of the Charity Commissioners informing the College that the Commissioners have at present under consideration proposals for a scheme of consolidating the British Lying-in Hospital, Endell-street, and the *Home for Mothers and Babies, Woolwich*, and constituting a managing committee for the administration of the "Maternity Hospital and School for the Higher Training of Midwives," to the establishment and maintenance of which at Woolwich it is desired that the funds of the consolidated charities should be made applicable. The Commissioners *inquired* whether the College would be prepared to nominate a representative of the College on the managing committee. It was resolved to consent to the proposition.

After some further formal business the PRESIDENT dissolved the Comitia.

Public Health.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On an Outbreak of Enteric Fever at Kenilworth, by Dr. E. P. MANBY.[1]—This report, which is illustrated by diagrams and a map, gives an interesting account of a small epidemic, affecting 44 persons, which lately occurred in the town of Kenilworth, and was clearly to be attributed to the pollution of the public water-supply. Forty-one of the cases were attacked between Nov. 22nd and Dec. 25th, 1913, 26 of these falling ill between Dec. 5th and 12th. The affected dwellings were scattered over the whole town; all were in the area supplied by the Kenilworth Waterworks Company, and no other source of epidemic infection, such as infected milk, was to be discovered. The water is partly obtained by pumping from two bore wells in the town, each over 200 feet deep, and provided that the tubes are sound and do not admit surface soakage, this portion of the supply is above suspicion in the matter of purity. After obtaining powers from Parliament in 1882 to supply water from wells, however, the company proceeded two years later to construct, in addition, what is termed in the report an "adit."

---

[1] Local Government Board Medical Reports, New Series, No. 90. London: Wyman and Sons, Fetter-lane; Edinburgh: H.M. Stationery Office; Dublin: E. Ponsonby. Price 1s.

but seems to have been merely a deep trench near the waterworks, which was bricked over and covered with earth. Ever since, until the recent outbreak, the company have continued to use the adit water as an integral or even as the main part of their supply, its use being particularly convenient, as it diminished the amount of pumping required. The adit intercepts water flowing underground towards the Finham Brook, and had an overflow into this stream, which was protected only by a flap cover, with the result that when the water in the stream was high a reverse flow into the adit could take place. This must have happened about the middle of November, at which time the Finham brook, which ordinarily receives the storm overflow from a section of the Kenilworth sewers at a point above the waterworks, was exceptionally polluted in consequence of one of the branch sewers having become blocked, thus bringing the storm overflow into operation. Among the earliest cases of the series was one which occurred early in November in a house draining to this branch sewer. Perhaps the most remarkable part of the story is the local ignorance which seems to have prevailed for so many years as to the existence of this substantial risk to the purity of the supply. Once the epidemic occurred and the water was looked into by the responsible authorities the source of pollution was self-evident. Dr. Manby considers that the principal reason that the risk has been so continuously ignored is "no doubt that the adit had so long been in existence that it was accepted by all concerned as an established source of supply, recognised by Parliament, and needing only occasional analytical checks rather as a matter of form than as an essential safeguard against an actual risk." As a fact, some of the analyses made in the past did give some indications that impurities might be gaining access to the water-supply, but these were not followed up. The report states that responsibility in these matters must rest with the water company. The district council might have done more in the way of control analyses, but they had not the facts as to the sources and origin of the supply fully before them, and in any case had no responsibility for furnishing a supply of good quality. The lesson of the outbreak is an old one, but there are probably not a few parts of the country where it can still profitably be learnt, and where the surroundings of local wells and the origin of the water should be inquired into without waiting either for an outbreak of water-borne disease or for a definite condemnatory analysis. The other feature of interest was the appearance between Nov. 19th and 25th of a general outbreak of gastro-enteritis in the town, almost immediately after the date on which the sewage pollution of the water of the adit appears to have occurred, and more than a week before the enteric fever became generally epidemic. This occurrence recalls the preliminary gastro-enteritis which has been reported in other water-borne epidemics in England and America. Dr. Manby notes that "gastric influenza" was prevalent in this part of Warwickshire at the time, and that this form of sickness was occurring about the same time in villages near Kenilworth which do not receive the Kenilworth water. On the whole, however, he concludes that the contaminated water-supply was responsible for a number of the cases of gastro-enteritis which so suddenly appeared in Kenilworth in the period in question. Some residents, both medical and lay, suggested that 50 per cent. of the inhabitants of the town were attacked by it, and all agreed that very few households escaped altogether. Some attacks were severe, but no deaths resulted. The enteric fever mortality itself was not severe; only 4 deaths occurred. The report testifies to the unremitting efforts of Dr. C. E. Tangye, the medical officer of health, and the officials of the district council and the waterworks company to deal with the outbreak. The advice of Dr A. C. Houston was obtained for the disinfection of the water mains, which was accomplished by the addition from a tank of sodium hypochlorite in quantity sufficient to run chlorinated water through the mains on the first day at a strength of 1 in 100,000, and on the second of 1 in 50,000.

REPORT OF THE MEDICAL OFFICER OF HEALTH OF JOHANNESBURG FOR 1912-13.

Dr. Charles Porter now has under his charge the public health of a population which exceeds a quarter of a million. The municipal area of Johannesburg measures about 11 miles across in one direction and nine in another, and by the standards of large English cities its resources for public works would be enormous, as its property has a value for rateable purposes of 33 millions, and in 1912–13 a 1*d.* rate produced about £100,000. The main water-supply, from deep wells in the dolomite at Zuurbekom, 18 miles west of Johannesburg, is said to be of exceptional purity, but a supplementary supply from the Klip River valley, to which surface water gains access, has been considered unsafe in its natural state, and for the past six years has been treated with chlorinated lime (guaranteed over 30 per cent. available chlorine) in the proportion of 13 lb. per million gallons. The results are stated to have been satisfactory. An after-process for softening the water has proved almost useless, and has been abandoned pending the introduction of a new scheme. Sewerage on the separate system is being extended, but the majority of the houses are served by a system of daily collection of night soil and slop-water, which are turned into the sewers at special intakes. Among other municipal services special reference should be made to the public abattoir, opened in 1910, the veterinary director of which contributes a report which shows that it has so far yielded a profit on the capital invested, and secures a very thorough means of satisfactory inspection of the meat supply. The percentage of tuberculous cattle is given at 0·13 and of tuberculous pigs 0·97. Reciprocity with other towns has been arranged in regard to meat inspection. Butcher's meat is admitted without charge into the Johannesburg municipal area if it bears the stamp of a municipality which has itself power to enforce meat inspection charges and admits free of charge butcher's meat bearing the Johannesburg meat stamp. Each municipality concerned, however, reserves to itself the right to subject the meat to any further inspection which seems necessary. A report on the circumstances of milk production in and around Johannesburg, made by the acting assistant medical officer of health, Dr. J. Pratt Johnson, is much less satisfactory. This report relates less to disease of milch-cows than to the contamination of milk by dirt, which appears commonly to take place on a considerable scale at many points on the way from the dairy to the consumer. Special complaint is made of the contamination which results from the usual practice of leaving the conduct of the dairy to Kaffirs, from the filthy water used for cleaning bottles and other dairy purposes, from access of flies, and other causes. Dr. Johnson's report contains a number of practical suggestions for improvement, and Dr. Porter, in an introduction to the report, urges the necessity for special dairy inspectors, and represents that, failing reforms effected by voluntary coöperation of farmers with the health authorities, the practicability of a large measure of municipalisation of the milk trade must be seriously considered. The general death-rate for 1912–13 was 19·49 per 1000; that among the white population, which numbers 134,000, was 11·3; among the natives 28·4; and the group of "Eurafricans and Asiatics" 24·4. The birth-rate of the white population remains high, 32 per 1000, and their infantile mortality rate was 99 per 1000 births. The death-rates from tuberculosis and miners' phthisis respectively during the year were, among the white population, 0·36 and 0·52; among the natives, 3·45 and 0·82; and among Eurafricans and Asiatics, 2·16 and 0·13. Pneumonia has, as usual, represented the principal cause of death among the native population. The Tuberculosis Commission appointed in 1912 has, in addition to a reference to investigate the extent and causes of the prevalence and spread of tuberculosis in various forms among all classes of the population, the duty of reporting on the extent and causes of the mortality among natives employed on the Witwatersrand mines and their susceptibility to pneumonia. The isolation hospital provision for Johannesburg appears to be made by the Government, the municipality being charged a fixed rate per case. A new isolation hospital is now to be erected. The occurrence of scurvy among some of the natives employed by the corporation has led to a careful study of their diet scale by Dr. P. G. Stock, who shows that it has fallen short considerably in protein, fat, and salt, and recommends an additional supply of bread and meat to make good these deficiencies, with a reduction in mealie meal, which when supplied should be in the form in which some of the germ and the husk are retained.

REPORTS OF SCHOOL MEDICAL OFFICERS.

County of Stirling.—Dr. T. Adam's report shows that the entrants, leavers, and two intermediate age groups of 7 and 10 years children were examined in the period under review. Much time is also given to special cases and reinspections. Only four or five per cent. of parents attend at the examinations. Nurse Gibson, school nurse, reports on following-up work and records an objection to treatment of a girl's squint by her mother, who said, "I've got a squint and I got a man, and surely she'll get a man even wi' her squint." The value of the report is very seriously reduced by the absence of index or contents.

Edinburgh School Board.—The schools in Edinburgh had 45,974 on the roll, and of these 26,173 were inspected during the year reviewed. Dr. J. Hally Meikle is able to record a successful experiment in providing meals at *5d.* a week for "semi-necessitous children." The average cost per meal was 1·7 pence, but this plan reduced the applicants for free meals. A good photograph is given of the cooking centre, and other pictures show the special and open-air schools. The Edinburgh Merchant Company Schools came for the first time into the system of medical inspection, and the children inspected varied from the age of 5 to 17 years. The character of the schools is unfortunately not made clear in the report, but they appear to correspond with high schools or secondary schools. Nutrition was much above the Edinburgh elementary school average in the Merchant Company Schools and above the anthropometric standard in nearly all cases.

Glasgow School Board.—In 10 schools in this area there are spray baths in operation and in 2 foot-baths. On one afternoon and two mornings an "examination clinic" is held by the chief medical officer, Dr. E. T. Roberts, at the offices of the board. Treatment of "necessitous" children is carried out under the education authority's direction by the work of eight part-time dentists, three anæsthetists, three oculists, one aurist, one dematologist, and six nurses. Skin diseases and ear discharge are also dealt with, favus and ringworm need special treatment, and an X-ray apparatus has been installed. 72·3 per cent. of the parents attend inspections. The report is well arranged and easy of reference, and contains useful matter concerning the various classes of special schools. The classes for semi-deaf, semi-mute, and young deaf children are continued.

Warwickshire County Council.—Dr. A. Bostock Hill's report shows that a very great deal of good work is being done, especially by the health visitors in the country districts. The distance difficulty is well brought out in the account of the mother who had to make a journey of 9 miles on 15 occasions, pushing a perambulator with the patient and a baby, to get treatment for ringworm. The same difficulty also has a considerable influence on the nutrition of school children, as those who live far from the school often bring with them "lunch" of an innutritious character. Important improvements have been made in school buildings, but indefensible "sanitary" conveniences appear to remain in connexion with too many.

Cambridgeshire County Council.—During 1912 the boundaries of the borough of Cambridge were extended and the county is now exclusively rural in character. Efforts are being made to cope with the problem of treatment, and arrangements exist for the provision of hospital letters to Addenbrooke's Hospital, for the purchase of spectacles, and for dental treatment. The hospital letter machinery, involving investigation by the education secretary, seems cumbrous. Only 41 per cent. of cases of enlarged tonsils and adenoids received treatment, and even this was an improvement on previous years. Dr. Frank Robinson notes the installing of a new type of sanitary pail which retains solid matter and permits the escape of liquid to a cesspool. Mr. A. W. Gant contributes a short report on the Stapleford dental clinic.

Huntingdonshire County Council.—Dr. C. B. Moss-Blundell hopes for the establishment of school clinics in connexion with the tuberculosis dispensaries. Advice is given to those who call at the medical officer's office on Saturday morning, and ringworm, skin disease, and cases referred from the school attendance officer have been seen. No other treatment agency as a part of the school organisation exists, and a large proportion of children go untreated.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 9059 births and 4938 deaths were registered during the week ended Saturday, May 2nd. The annual rate of mortality in these towns, which had been 15·0, 14·9, and 15·1 per 1000 in the three preceding weeks, declined to 14·2 per 1000 in the week under review. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 14·8, against 13·8 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 5·9 in Swindon, 6·6 in Eastbourne, 7·9 in Wimbledon, 8·3 in Coventry, and 8·4 in Willesden, to 20·6 in South Shields, 21·9 Middlesbrough, in West Hartlepool, and in Swansea, 22·0 in Plymouth, and 23·2 in Barnsley.

The 4938 deaths from all causes were 321 fewer than the number in the previous week, and included 453 which were referred to the principal epidemic diseases, against 438 and 445 in the two preceding weeks. Of these 453 deaths, 155 resulted from measles, 139 from whooping-cough, 59 from infantile diarrhœal diseases, 50 from diphtheria, 35 from scarlet fever, and 15 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3 per 1000, and coincided with the rate in the two preceding weeks. The deaths attributed to measles, which had been 134, 153, and 140 in the three preceding weeks, rose to 155 last week, and caused the highest annual death-rates of 1·7 in Rochdale and in Sheffield, 1·8 in Merthyr Tydfil, 2·0 in Smethwick, 2·9 in Barnsley, 3·0 in Dudley, and 3·5 in Stockton-on-Tees. The deaths referred to whooping-cough, which had been 150, 117, and 166 in the three preceding weeks, declined to 139 last week; the highest death-rates recorded from this disease were 1·1 in Stoke-on-Trent, 1·2 in Middlesbrough and in Newport (Mon.), 1·3 in Gateshead and in Swansea, and 1·7 in Enfield. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 54, 61, and 66 in the three preceding weeks, fell to 59 last week, and included 17 in London, 5 in Manchester, 4 in Birmingham, 3 in Liverpool, and 3 in Sheffield. The deaths attributed to diphtheria, which had been 44, 50, and 40 in the three preceding weeks, rose to 50 last week; of this number, 8 were recorded in London, 8 in Birmingham, 3 in Liverpool, 3 in Bradford, and 2 each in Tottenham, Leyton, and Stoke-on-Trent. The deaths referred to scarlet fever, which had been 39, 40, and 23 in the three preceding weeks, rose to 35 last week, and included 5 in London, 5 in Liverpool, 3 in Birmingham, and 3 in Sheffield. The fatal cases of enteric fever, which had been 12, 17, and 10 in the three preceding weeks, rose to 15 last week, of which 3 occurred in London and 2 in Manchester.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had declined from 3182 to 2886 in the four preceding weeks, had further decreased to 2876 on Saturday last; 377 new cases were admitted during the week, against 306, 289, and 305 in the three preceding weeks. These hospitals also contained on Saturday last 1129 cases of diphtheria, 336 of whooping-cough, 104 of measles, and 55 of enteric fever, but not one of small-pox. The 1116 deaths from all causes in London were 132 fewer than the number in the previous week, and corresponded to an annual death-rate of 12·9 per 1000. The deaths referred to diseases of the respiratory organs, which had been 219, 263, and 258 in the three preceding weeks, further declined to 185 in the week under notice, and were 60 below the number recorded in the corresponding week of last year.

Of the 4938 deaths from all causes in the 97 towns, 151 resulted from various forms of violence, and 341 were the subject of coroners' inquests, while 1403 occurred in public institutions. The causes of 31, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 71 other smaller towns. Of the 31 uncertified causes of death, 4 were recorded in Liverpool, 3 in Birmingham, and 2 each in London, Bootle, Warrington, Manchester, Blackburn, and Hull.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1283 births and 669 deaths were registered during the week ended Saturday, May 2nd. The annual rate of mortality in these towns, which had been 16·5, 16·0, and 16·9 per 1000 in the three preceding weeks, declined to 15·2 per 1000 in the week under review. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 16·2, against a corresponding rate of 14·8 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 7·6 in Kirkcaldy, 8·2 in Clydebank, and 9·4 in Falkirk, to 19·1 in Kilmarnock, 20·6 in Coatbridge, and 21·4 in Motherwell.

The 669 deaths from all causes were 72 fewer than the number in the previous week, and included 61 which were referred to the principal epidemic diseases, against 55 and 71 in the two preceding weeks. Of these 61 deaths, 19 resulted from measles, 17 from infantile diarrhœal diseases, 13 from whooping-cough, 8 from diphtheria, 2 from scarlet fever, and 2 enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·4, against 1·3 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 31, 20, and 29 in the three preceding weeks, declined to 19 last week, of which 11 occurred in Glasgow, 3 in Edinburgh, and 2 in Dundee. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 5, 13, and 18 in the three preceding weeks, were 17 last week, and included 8 in Glasgow, 3 in Aberdeen, and 2 in Dundee. The fatal cases of whooping-cough, which had declined from 15 to 9 in the four preceding weeks, rose to 13 last week, of which 8 were recorded in Glasgow and 3 in Coatbridge. The deaths attributed to diphtheria, which had been 7, 4, and 9 in the three preceding weeks, were 8 last week, and included 2 in Glasgow and 2 in Edinburgh. The deaths referred to scarlet fever, which had been 6, 7, and 4 in the three preceding weeks, further fell to 2 last week, and were recorded in Glasgow and Dundee. The 2 fatal cases of enteric fever, which were equal to the average in the three preceding weeks, were registered in Glasgow and Dundee.

The deaths referred to diseases of the respiratory system, which had been 137, 120, and 130 in the three preceding weeks, declined to 90 in the week under notice; and 28 deaths resulted from different forms of violence, against 29 and 31 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 712 births and 477 deaths were registered during the week ended Saturday, May 2nd. The annual rate of mortality in these towns, which had been 20·3, 22·5, and 25·3 per 1000 in the three preceding weeks, declined to 20·6 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 22·2, against corresponding rates of 14·8 and 16·2 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 24·5 in Dublin (against 12·9 in London and 14·8 in Glasgow), 18·2 in Belfast, 23·1 in Cork, 19·0 in Londonderry, 23·0 in Limerick, and 20·9 in Waterford, while in the 21 smaller towns the mean rate did not exceed 16·9 per 1000.

The 477 deaths from all causes were 107 fewer than the number in the previous week, and included 63 which were referred to the principal epidemic diseases, against 75 and 69 in the two preceding weeks. Of these 63 deaths, 45 resulted from measles, 9 from whooping-cough, 8 from infantile diarrhœal diseases, and 1 from scarlet fever, but not one from enteric fever, diphtheria, or small-pox. The mean annual death-rate from these diseases last week was equal to 2·7 against corresponding rates of 1·3 and 1·4 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 37, 42, and 37 in the three preceding weeks, rose to 45 last week, of which 40 occurred in Dublin and 3 in Belfast. The deaths referred to whooping-cough, which had been 9, 14, and 12 in the three preceding weeks, further declined to 9 last week, and comprised 4 in Cork, 3 in Belfast, and 2 in Dublin. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 8, 10, and 7 in the three preceding weeks, were 8 last week, of which 4 were recorded in Belfast and 3 in Dublin. The death from scarlet fever was registered in Belfast.

The deaths referred to diseases of the respiratory system, which had been 102, 115, and 112 in the three preceding weeks, further fell to 57 in the week under notice. Of the 477 deaths from all causes, 135, or 29 per cent., occurred in public institutions and 8 resulted from various forms of violence. The causes of 15, or 3·1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes did not exceed 0·6 per cent.

A CENTENARIAN.—Mr. John Turner, a handloom weaver of Kirkburton, near Penistone, has died in his 101st year.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Deputy Surgeon-General William Maxwell Craig, C.B., has been promoted to the rank of Surgeon-General in His Majesty's Fleet (dated May 1st, 1914).

Scott, civil surgeon at Sylhet, has been transferred to the Khasi and Jaintia Hills as Civil Surgeon of that district. Captain H. A. H. Robson has been appointed to officiate as Superintendent of the Central Lunatic Asylum at Berhampore *pro tem.* Captain C. L. Dunn has been granted five months' extension of leave of absence home from India on medical certificate. Captain G. A. Jolly has been granted nine months' leave of absence. Captain A. F. Babonau has been appointed to officiate as Civil Surgeon of the Naga Hills District. Captain W. W. Jeudwine has been appointed Plague Medical Officer to the Jhelum District. Captain C. H. Brodribb has been appointed Specialist in Advanced Operative Surgery.

COLONIAL MEDICAL SERVICES.

West African Medical Staff.—Mr. G. F. Forde has been transferred from the Gold Coast to Nigeria; Dr. J. A. Harley and Mr. S. L. Brohier from the Gambia to the Gold Coast; Mr. J. C. Franklin from the Gambia to Nigeria; and Mr. G. Rollason from Sierra Leone to Nigeria. The following have resigned: Dr. A. Lundie (medical officer, Gold Coast), Dr. E. J. Wyler (medical officer, Nigeria), and Dr. A. Hutton (medical officer, Nigeria). Dr. A. Bremner (medical officer, Sierra Leone) has retired on pension. The following have been selected for appointment to the staff: Dr. T. P. Fraser (Nigeria) and Dr. A. S. Burgess (Gold Coast). The following promotions have been made: Mr. T. Hood from principal medical officer, Nigeria, Southern Provinces, to Director of the Medical and Sanitary Service of Nigeria; Mr. E. A. Chartres from senior medical officer, Gambia, to a Senior Medical Officer (Grade I.) Nigeria; Dr. C. R. Chichester from provincial medical officer, Southern Nigeria, to Senior Medical Officer (Grade I.), Nigeria; Mr. W. H. G. H. Best from provincial medical officer, Southern Nigeria, to a Senior Medical Officer (Grade I.), Nigeria; Mr. C. F. Watson from senior medical officer, Northern Nigeria, to Senior Medical Officer (Grade II.), Nigeria; Dr. W. H. A. Gordon-Hall from medical officer, Northern Nigeria, to a Senior Medical Officer (Grade II.), Nigeria; Mr. W. I. Taylor from senior medical officer, Northern Nigeria, to a Senior Medical Officer (Grade II.), Nigeria; Mr. H. P. Lobb, medical officer, Northern Nigeria, to a Senior Medical Officer (Grade III.), Nigeria; Dr. M. E. O'Dea from medical officer, Southern Nigeria, to a Senior Medical Officer (Grade III.), Nigeria; Mr. W. W. Claridge from medical officer, Gold Coast, to a Senior Medical Officer (Grade III.), Gold Coast; Dr. A. E. Horn from personal assistant to the principal medical officer, Southern Nigeria, to Senior Medical Officer (Grade III.), Gambia; and Dr. J. M. Dalziel from medical officer, Northern Nigeria, to a Sanitary Officer, Nigeria.

Other Colonies and Protectorates.—Mr. N. S. Williams has been selected for appointment as a temporary Medical Officer in Uganda; Dr. J. H. Paterson as a Supernumerary Medical Officer in Jamaica; Mr. C. H. Sills and Dr. S. Vassallo as Supernumerary Medical Officers in the Leeward Islands; Mr. W. A. S. George; as a District Medical Officer in St. Vincent; and Dr. H. P. Hacker as a Supernumerary Medical Officer in the Federated Malay States.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Captains, Army Medical Reserve, to be Captains, retaining their rank and seniority (dated May 1st, 1914): John Findon Murphy and Murray Ross Taylor.

Lieutenant Vivian R. Smith resigns his commission (dated May 6th, 1914).

Cadet John Alston, from the Glasgow University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated April 6th, 1914). Cadet Charles Robertson McIntosh, from the Glasgow University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated April 8th, 1914). John Cameron to be Lieutenant (on probation) (dated April 9th, 1914).

Army Medical Reserve.

Captain Samuel K. Adams is removed on completion of the period of service prescribed by Article 641, Royal Warrant for Pay and Promotion, 1907 (dated April 30th, 1914).

Lieutenant Alfred S. Millard is removed on completion of the period of service prescribed by Article 641, Royal Warrant for Pay and Promotion, 1907 (dated Jan. 31st, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd West Lancashire Field Ambulance, Royal Army Medical Corps: Lieutenant-Colonel Thomas Stevenson.

3rd North Midland Field Ambulance, Royal Army Medical Corps: Supernumerary Lieutenant William Boyd is absorbed into the establishment (dated Jan. 21st, 1914).

Major Edgar Thomas Inkson, V.C., Royal Army Medical Corps, to be a Deputy Assistant Director of Medical Services of a Territorial Division (dated April 25th, 1914).

For Attachment to Units other than Medical Units.—Frank Harris White to be Lieutenant (dated April 17th, 1914).

Attached to Units other than Medical Units.—Lieutenant Leonard Colebrook to be Captain (dated April 3rd, 1914).

Major David Middleton Greig, attached to the 2nd Highland Brigade, Royal Field Artillery; Major Samuel Lodge, attached to the 6th Battalion, The Prince of Wales' Own (West Yorkshire Regiment); Major Thomas Forrest, attached to 7th Battalion, The Cameronians (Scottish Rifles); Major James Duncan Farquharson (unposted).

THE TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned Officers of the Territorial Force: Lancashire (Fortress) Engineers, Royal Engineers: Surgeon-Major John Wesley Lloyd.

ROYAL ARMY MEDICAL COLLEGE.

On May 1st Lieutenant-General Sir James Grierson presented the prizes at the Royal Army Medical College to the junior class of the twenty-fourth session, in the presence of a large gathering of officers, visitors, and ladies. Colonel B. M. Skinner, commandant of the school, was supported by Major-General Sir Francis Lloyd, Surgeon-General Sir Launcelot Gubbins, Surgeon-General Sir Arthur

Sloggett, Surgeon-General Cuff, Surgeon-General Whitehead, Surgeon-General Trevor, Surgeon-General Bassett-Smith (of the Naval School, Greenwich), Sir Ronald Ross, and others. Colonel Skinner, in the opening remarks, said that the course of instruction at the Royal Army Medical College was constructed to bear essentially on the health and training of the soldier. He said the results of the examinations had been very gratifying, and that special instruction had been given also in administrative methods. General Grierson, in presenting the prizes, told the students that they were joining one of the finest branches of the service, and one which had developed more than others in recent years. They had only to compare what took place in the Crimean war with what was done in South Africa to realise the great advances made in the medical service of the army. The present medical organisation was extended also to the Territorial Forces. He emphasised the double aspect of the army medical officer, who was both a soldier and a doctor, and reminded them that their purely professional and technical duties were secondary to their duties as soldiers and officers of the King. This meant double work for them. Surgeon-General Gubbins, in proposing a vote of thanks to General Grierson, emphasised the value of his words as coming from one of wide knowledge and experience of home and foreign armies. After the prize distribution Colonel Skinner and the officers of the Royal Army Medical Corps entertained their visitors in the officers' mess.

INDIAN MEDICAL SERVICE DINNERS.

The annual London dinner of the Indian Medical Service will be held at the Hotel Cecil on Monday, June 8th, at 7.45 P.M. The Edinburgh dinner of the Indian Medical Service will be held on May 29th at the Caledonian United Service Club, when Sir Alexander Christison, Bart., will preside. Application for tickets should be made to Colonel Arnott, 8, Rothesay-place, Edinburgh.

The Senate of Glasgow University have decided to confer the honorary degree of LL.D. upon Colonel Sir William B. Leishman, professor of pathology at the Royal Army Medical College.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

MANCHESTER.

National Insurance Act: The Payment of the Panels.

THE Manchester Insurance Committee have decided to make a payment to the medical men for the first quarter of this year at the rate of 40 per cent. on the accounts sent in. This will use up £15,771. The committee retained 25 per cent. of the medical credits at the end of last year in order to meet any substantial claims by the chemists in respect of over-prescribing. The chemists have formulated their claims, and it appears that the committee will have a balance of £7761 to allocate amongst the doctors.

Hospital Matters in and about Manchester.

The Ancoats Hospital, which is situated in a densely populated part of Manchester and adjacent to many public works, is making an appeal for £450 for sanitary improvements and for the construction of a new ward at the cost of £2500. In an appeal which has been issued by the chairman it is stated that the present 114 beds are totally inadequate to deal with the proportion of the 33,000 cases per annum which require indoor treatment, and the effect of the National Insurance Act has been to reveal much suffering hitherto unrelieved through fear of incurring expense. At the annual meeting of the St. John's Hospital and Manchester Ear Hospital the authorities have noticed since the Insurance Act came into operation a very great increase in serious cases. Not so many patients passed through the beds, but they remained longer, because they were more serious cases sent by the doctors for treatment which was not provided for under the Insurance Act. The governors of the Ashton, Stalybridge, and Hyde District Infirmary have decided to enlarge their hospital at an outlay of £25,000. For this purpose additional land is required, and the estate trustees of Lord Stamford will give three acres subject only to the repayment of the cost of road-making. Lastly, the fund for the Central Branch of the Royal Infirmary has now reached £19,520, £567 having been received since the last meeting of the board of management. Mrs. George A. Southam, of Hale, Cheshire, has generously offered to provide the sum of 50 guineas per annum towards the payment of a pathologist or assistant pathologist, and intends to set aside the capital sum, duly secured to the hospital, to provide this income. The bequest will be known as the "Southam Pathological Bequest." There is general evidence that Manchester people intend to help their medical charities in these critical times.

A Home of Recovery for Children.

A small committee has established a home at Heptonstall, near Hebden Bridge, where a number of weak and ailing children are given a prolonged holiday to nurse them back to health, most of them outcasts from our system of medical treatment because they have no direct illness which would entitle them to hospital benefit. They are the children of the slums of Hulme and Ancoats, where delicate children have no chance to grow up healthily. The children live an outdoor life, are taught what will be useful to them, and encouraged to work and play in the open air. The building stands among the moors, 900 feet above sea level. The establishment is supported by private contributions, and an appeal is being made for funds to continue the work.

Radium for Manchester and Salford Hospitals

I referred recently to the Radium Fund. The general committee have now issued a complete scheme and an appeal for funds. The sum required is £25,000 for the purchase of radium and radioactive materials. In all seven hospitals in Manchester and Salford will participate in the scheme. The radium and mesothorium when obtained will be deposited at the Royal Infirmary, where patients will be sent for treatment. The radium committee intend to appoint a physicist to give his whole time to the work of the radium department, and an expert radiologist to advise as to the line of treatment, dosage, &c., and to conduct treatment when necessary.

May 5th.

BIRMINGHAM.

General Hospital: Resignation of Sir Robert M. Simon.

A CONSIDERABLE change is taking place in the *personnel* of the staff of the General Hospital. Two years ago Dr. Robert Saundby, senior physician, and Sir Thomas Chavasse, senior surgeon, resigned their posts after many years of faithful service. Now the hospital is about to experience another great loss by the resignation of the present senior physician, Sir Robert Simon. Other important changes must take place during the next few years owing to the operation of the time limit. At a meeting of the board of management on May 1st the following resolution was unanimously passed:—

> That the board of management have received with great regret the resignation of Sir Robert M. Simon, senior honorary physician, and desire to record their high

appreciation of the very able manner in which he has discharged his duties as honorary physician for the past 23 years, of the great skill and attention he has devoted to the patients under his care, and of the interest he has taken in the welfare of the institution. That the resignation of Sir Robert M. Simon be accepted with great regret, that the office of honorary physician be declared vacant, and that steps be taken to fill the vacancy on Friday, May 22nd, 1914, at 12 o'clock noon. That a subcommittee be appointed to consider what steps should be taken to commemorate Sir Robert M. Simon's services to the hospital, and that at the next meeting of governors it be recommended that in consideration of the eminent services rendered to the hospital during the past 35 years by Sir Robert M. Simon he be appointed honorary consulting physician to this hospital.

Sir Robert Simon came to Birmingham as assistant physician to the General Hospital after three years' very successful work as honorary physician to the Manchester Southern Hospital for the Diseases of Women and Children. In 1891 he was elected honorary physician. He became a Fellow of the Royal College of Physicians of London in 1895, and was knighted in 1910. Since 1910 he has been professor of therapeutics in the University of Birmingham and has held the post of professor of forensic medicine at Mason's College. He is consulting physician to many local hospitals.

Conference of Nurses.

The annual conference and nursing exhibition convened by the National Council of Nurses will be held in the New Central Hall, Birmingham, from June 9th to 12th. Mr. H. Gilbert Barling, Vice-Chancellor of the University of Birmingham, and Miss Rogers, late matron of the Royal Infirmary, Leicester, will present the case for nurses' registration. Mrs. Bedford Fenwick will speak of the Nurses' International Memorial to Miss Florence Nightingale. Miss Musson, matron of the General Hospital, Birmingham, will be the chief speaker in the economic section, and there are quite a number of questions to be discussed in connexion with it. Sir Victor Horsley will advocate the necessity for nursing as part of medical benefit for insured persons, and several topical questions will be brought forward.

Medical Work in Schools.

Dr. G. A. Auden, the school medical officer, in his report for 1913 states that two notable advances were made in the direction of treatment—viz., the initiation of dental treatment and of a scheme for the operative treatment of tonsils and adenoids.[1] The scheme for the erection of a properly equipped central school clinic in Great Charles-street has received the sanction of the Board of Education and the land has been bought. The treatment of certain minor external ailments has been begun and the staff of nurses increased. The development of this scheme of treatment may be said to mark the close of the first phase of the evolution of the school medical service. Since 1908 there has been a regular sequence of effort—viz., (1) medical inspection of children on entering and leaving school; (2) following up of individual children found defective and facilities for special examinations at the clinics and in the schools; (3) the special recording of tuberculous, epileptic, physically handicapped, and ringworm cases; (4) treatment for eye defects, teeth defects, tonsils and adenoids, ringworm, and external minor ailments; (5) the general guidance in the choice of suitable work on leaving school. The number of children inspected in each year was as follows: 1908 (September to December, with three officers), 9404; 1909, 26,484; 1910, 24,363; 1911 (three full-time and three part-time officers), 28,067; 1912, 34,224; 1913, 32,376; giving a total of 154,918. Dr. Auden thinks that the next stage of development must be coöperative and that every effort must be made to correlate the medical work, not only with the march of educational administration, but also with all the ameliorative agencies which are already dealing with child life. The percentage of parents who were present at the examination of their children was 72. The defects discovered during 1913 were: Defects of vision, all causes, 3265; squints, 969; corneal ulcers, opacities, and keratitis, 308; defective hearing, 1084; otorrhœa, 666; tonsils and adenoids, 2550; certain phthisis, 100; doubtful phthisis, 215; other lung diseases, 645; heart disease, congenital 93, acquired 489; chorea, 85; epilepsy, 83; hernia, 81; speech defects, 225; deformities (excluding paralysis) 277; ringworm, 243; and skin disease, 372.

May 5th.

SCOTLAND.

Interesting Legal Judgment.

THE House of Lords recently gave judgment in an appeal case brought by the widow of a Rutherglen miner. The man, who had been sweating at his work, caught cold while waiting at a mid-landing in the mine until men from the lower seam had been raised. This developed into pneumonia, which proved fatal. The sheriff found that the man had died from the effects of injuries by accident received at his work, and allowed compensation. The Second Division, however, recalled this award, and found the present respondents entitled to expenses. The House of Lords restored the finding of the sheriff (acting as arbitrator), Lord Shaw of Dunfermline making a statement.

Edinburgh Corporation and the Veterinary Department.

There is a scheme before the authorities proposing to set up a separate veterinary department in the city. At present there are four veterinary surgeons who carry out this work of the corporation, acting on the instruction and under the supervision of the medical officer of health. A report just issued states that the work did not include any of the duties to be discharged by a veterinary surgeon under the supervision of the Contagious Diseases (Animals) Act. A considerable amount of veterinary work was required in connexion with the stud of horses for the cleansing department. This work was carried out by the professors of the Royal Dick Veterinary College, under an arrangement with the corporation. With the exception of the senior veterinary officer, the maximum salary of each of the veterinary surgeons on the staff was at present £175 per annum. The maximum salary of the senior veterinary officer was at present £200 per annum. The subcommittee was of opinion that the veterinary work of the corporation was so intimately connected with the public health work of the city, particularly as regards the meat and milk supplies, that it was of great importance that it should be carried out under the direct administration, supervision, and control of the medical officer of health. It appeared to be desirable that a considerable amount of responsibility and initiative supervision should rest with the senior veterinary officer, and the committee recommended that the appointment should be made on recommendation to the medical officer of health, with the approval of the town authorities. Among the more important duties of this "senior veterinary officer" would be inspecting the city byres, the milk-supply where necessary, attending the slaughter-houses while slaughtering operations were being carried out, and the general meat and food inspection in the market, railway stations, and shops.

---

[1] THE LANCET, Jan. 10th, 1914, p. 132.

Housing Conditions at Rosyth Naval Base.

On account of recent interest excited in this subject, the annual report of Dr. A. S. Gordon, medical officer of health, is of importance. Dealing with the housing question, he states that since the report of Dr. T. F. Dewar and Mr. Wilson, of the Local Government Board, the housing conditions available at the naval base had very materially improved. At that time it was stated that the navvies temporarily housed within the borough of Inverkeithing were accommodated in a satisfactory manner, to which little or no exception could be taken. In 1911 a new model lodging-house, with 152 beds, was completed, and until recently that building had not been fully occupied. In April, 1913, the White House Hotel was opened. That house, which provided accommodation for 300 men of the better class of workmen, had not been fully occupied until the end of November, 1913. Since the report by these representatives of the Local Government Board new houses and tenements had also been completed and occupied. The demand had also been relieved by the erection of huts at Rosyth, and the running of special trains to Dunfermline. It had been found that the demand for ordinary houses of one-room and kitchen, or two rooms and kitchen, had much diminished. Houses of a larger and better type—four rooms and kitchen—were now found to be in request. A considerable number of workers at the paper mill had been thrown out of employment by a disastrous fire, and as many then left the district more accommodation was available for the Admiralty workers. For the better control and the prevention of overcrowding, by-laws for houses let as lodgings had been adopted. The appointment of an additional sanitary inspector, who also acted as borough surveyor, should also prove an advantage.

Work of the Edinburgh Insurance Committee.

A report has been prepared by the clerk on the administrative work of this committee from July, 1912, to April, 1914. As there is an unexpended balance in the drug fund a substantial bonus will shortly be paid over to the local panel chemists. Of 21 complaints brought against practitioners on the panel only six were upheld. For insurance service work the incomes of panel practitioners were as follows:—

Over £900	1	Over £300	12
,, 800	1	,, 200	15
,, 700	4	,, 100	16
,, 600	7	,, 50	4
,, 500	10	Under 50	39
,, 400	12		

The highest number of insured persons on any one list was 2903, the lowest being three. The highest amount paid to any one practitioner was £933 13s., and the lowest amount was 8s. 8d. Since the commencement of the medical benefit to the present time practitioners on the panel have received £39,931.

Accommodation of Phthisis Patients in Glasgow.

Negotiations have been taking place recently between the corporation of Glasgow and Govan parish council with regard to the treatment of patients suffering from phthisis. A deputation from the corporation subcommittee visited Merryflatts hospital, which belongs to the parish council of Govan, and after inspecting the various buildings, suggested that the parish council should place at the disposal of the corporation the recently erected phthisis wards, or as many of these as might be found necessary, together with the adjoining chalets. After considering the matter the parish council, for administrative and other reasons, have decided not to hand over these, but will enter into a temporary arrangement with the corporation for boarding their patients to the extent of the accommodation available.

Dundee Panel Committee and Medical Grievances.

The Dundee Panel Committee have entered a protest to the Insurance Committee against the system whereby the medical profession were being penalised for all the defects arising in every department in the administration of medical benefit. They also urge the delivery of a medical card to every insured person; otherwise, in view of the difficulties which have arisen, they will feel it their duty to advise practitioners to refuse medical attendance to any person who does not produce such a card. 12,000 of the new medical cards had been returned undelivered, and on the cards which had been delivered the entry of the doctor's name had been erroneous in a great number of cases, and it was within the knowledge of the committee that insured persons who had been aggrieved by these mistakes found difficulty in having them corrected. The responsibility for the medical benefit of insured persons had not been removed from the doctors; but owing to these mistakes a large number of insured persons entitled to medical benefit were for the time being removed from the doctors' lists. These lists, which had not yet been delivered, and which were the doctors' only warrant for payments, had thus been seriously lessened, although the doctors' responsibilities had in no way diminished. The grievance had been further aggravated by the instructions issued that an insured person who furnished the clerk with what he considered sufficient evidence of being entitled to medical benefit had to be provided with a medical card, although he had not been authenticated officially by an index slip, without which the clerk had no guarantee for a credit to the cost of that person's medical benefit as an individual. The committee felt bound to put before the Insurance Committee a demand that, as stipulated by the agreement, payment be made for every medical card issued, whether the insured person had been duly authenticated or not.

May 5th.

IRELAND.

The British Medical Association and Ireland.

As was anticipated, the increase of the subscription to the British Medical Association has caused a definite diminution in the number of members in Ireland. Recently it was as high as 1000, but it has now fallen to 756. The Council, having considered the matter, has decided to open an office in Ireland in order to organise the profession of Ireland under the Association. A whole-time medical secretary has been appointed to take charge of the office. The task is not likely to be an easy one, though the Council has been fortunate in securing the services of a gentleman who possesses considerable influence with the profession, particularly in the country districts. At present the representative body of the profession in Ireland is the Irish Medical Committee, which is formed mainly of delegates from the several Local Medical Committees. It is a strong body, possessing the confidence of the whole profession, but it is admitted that its financial basis is weak. Since its formation the Irish Medical Association and the British Medical Association have recognised it as the representative committee of the profession. It seems, however, as though the British Medical Association were now about to demand for its Irish Committee a representative status. The problems of Irish medical politics will not, I fear, be rendered simpler by the new move of the British Medical Association.

Dublin Corporation Tuberculosis Hospital.

At its last meeting the Dublin corporation proceeded to the election of two visiting physicians for the tuberculosis hospital on the Pigeon House-road. Prior to the corporation taking over this institution a few months ago it was managed by the Women's National Health Association for several years under the name of the "Allan A. Ryan Home Hospital." For the greater part of the time that it was in the hands of the association two gentlemen gave their services voluntarily as visiting physicians. They were both candidates for the posts in the service of the corporation, but their applications were passed over. A legal point was raised at the election as to whether such appointments should be made by the corporation itself or by the tuberculosis committee. The Act of Parliament seems to be clear that the entire management of tuberculosis hospitals is in the hands of the committee. The town clerk, however, advised that the election rested with the corporation. The point is not of immediate importance, since the tuberculosis committee, as at present constituted, consists of all the members of the corporation.

Irish Workhouses.

During the year ended Sept. 30th, 1912, the amount spent on Poor-law in Ireland was £1,012,230, and to this must be added £269,655, the expenditure under the Medical Charity and other Acts, giving a total of £1,281,885. In the previous decade the corresponding figures were: Poor relief £965,720 and medical charities £210,166, producing a total of £1,175,886. Judging by unions, the largest union in Ireland is the South Dublin, where the daily average number of inmates was 3914. Belfast comes next with 3233, and North Dublin is third with 2309. This makes a total for Dublin of 6223, compared with Belfast's 3233. The average cost of in-maintenance per head per week in the South Dublin union is 4*s.* 9*d.*, in the North Dublin 4*s.* 2*d.*, and in Belfast 4*s.* 0¾*d.* In 1895 the figures were: South Dublin 3*s.* 5¾*d.*, showing an increase of 36½ per cent., to 4*s.* 9*d.* in 1912; North Dublin 3*s.* 3¼*d.*, showing an increase of 27½ per cent., to 4*s.* 2*d.* in 1912; Belfast 3*s.* 1¼*d.*, showing an increase of 31 per cent., to 4*s.* 0¾*d.* in 1912.

Infectious Diseases in Belfast.

Between March 16th and April 18th, 1914, 263 cases of infectious disease have been notified in Belfast, including 8 cases of typhoid fever, 33 of diphtheria, and 197 of scarlet fever; 19 cases of pulmonary tuberculosis have also been notified. In the previous five weeks 268 cases of infectious disease were notified, and 186 in the corresponding period of last year. It is remarkable how the scarlet fever epidemic still continues in Belfast. Notification, isolation, and hospital treatment all seem to have no effect in lessening its occurrence.

Dr. J. S. Darling.

Dr. J. S. Darling, who has been for the past 24 years medical officer of the Lurgan workhouse, was on April 30th at a specially summoned meeting of the Lurgan board of guardians unanimously granted an increase of £50 per annum to his salary. To his numerous medical friends this recognition, though tardy, of Dr. Darling's services has given the utmost satisfaction. Dr. Darling takes a keen interest in the scientific advancement of medicine and surgery.

May 5th.

PARIS.

The Dangers of Methylated Spirits in Iodine Disinfection.

IODINE disinfection is largely employed in France to-day, especially for the operator's hands. About 10 c.c. of tincture of iodine are put into half a litre of alcohol, and the surgeon rinses his hands therein, often in the operating theatre itself, before beginning to operate. At the Hôpital de Clermont-Ferrand, in the service of Professor Bousquet, serious accidents have occurred owing to the substitution by the hospital administration of "denatured" alcohol (methylated spirits) for pure alcohol, on account of its much lower cost, the tax being greatly reduced on the denatured kind. From the time that this was substituted it was observed that irritant vapours were disengaged from the solution as soon as the administration of chloroform began, which caused tingling of the eyes and nostrils, cough, and suffocation in all present in the operating theatre. It seemed as though some gaseous combination was formed between the vapours of iodine, methylated spirits, and chloroform. Even the anæsthetised patients were affected, and two patients in succession were seized with serious syncope, necessitating rhythmic tongue traction and artificial respiration for their recovery, while a subsequent patient died, notwithstanding the practice of these measures. The suppression of denatured alcohol was then decided on, and pure alcohol was again used, when these accidents ceased. Dr. Pakowski, who reports these cases, concludes that methylated spirits must not be used, or at least that the rinsing of the hands must be carried out with it in a room shut off from the operating theatre and well ventilated.

Measures against Leprosy.

The Académie de Médecine has voted the following administrative measures against the spread of leprosy in France: (1) Leprosy to be made compulsorily notifiable; (2) lepers to be submitted, according to circumstances, to either special surveillance or isolation; (3) foreign lepers not to be allowed to land in France; (4) a special Commission, constituted as laid down in the Bill before Parliament, to decide upon each case; (5) the academy cannot deal with the prophylaxis of leprosy in France without urging on the public authorities the necessity for rigorous and indispensable measures to control the diffusion of leprosy in the colonies and protectorates, which are infinitely more menaced than France itself. M. Gaucher extolled the total interdiction of French territory, at home and in the colonies, to foreign lepers, the isolation in an island off the coast of French lepers who had been infected in the colonies, and a distinction between these last, who are particularly dangerous from the point of view of contagion, and the autochthonous lepers of the Mediterranean littoral or of Cantal, in whom the leprosy is attenuated and comparatively harmless.

The Wassermann Reaction in Medical Jurisprudence.

Accepted views as to the relation between general paralysis and syphilis seem likely to provide lawyers with a further argument which can be invoked in a plea of irresponsibility. Last year a very enterprising business man, who had simultaneously floated a large number of diverse industries, was arrested at the suit of his numerous dupes. Many millions of francs had been swallowed up in his undertakings. He is at present in prison, and his lawyers are now demanding his release on the ground of irresponsibility. They contend that his feverish activity, the multiplicity of his unrelated enterprises, and his insurmountable optimism are stigmata of general paralysis. In support of their views they have had the Wassermann test applied to their client, and it has proved positive. The court has appointed experts to decide whether the Wassermann reaction is really sufficient ground to establish irresponsibilty in a case of fraud involving many millions.

The International Conference Against Alcoholism.

The International Conference Against Alcoholism met in Paris last week at the Musée Social, under the presidency of Professor Debove. Dr. Lauer proposed the establishment of an international institute for the scientific study of the subject. M. Aubert discussed the relations between anti-alcohol societies and other social works, such as the fight against tuberculosis, infant mortality, and unhealthy dwellings. M. Duteuil and Dr. Hartford, of London, discussed the anti-alcohol warfare in the colonies. M. Filassier, head of the statistical bureau of the city of Paris, demonstrated the incompleteness of statistics based upon the returns of the fiscal administration. He showed that in France the privilege of the "bouilleurs de crus" causes a formidable margin of doubt, for it allows all producers of fermented liquors to distil, without any control or account thereof taken, the product of their crop, nominally for personal consumption. This product is often fraudulently sold, so that the alcoholic consumption is really much greater than is shown by revenue statistics, and it can be easily demonstrated by medical statistics that the departments in which this privilege is in force are those that furnish the greatest number of alcoholic subjects, and of diseases caused or aggravated by the abuse of alcohol.

May 4th.

VIENNA.

University of Vienna.

THE programme of lectures during the summer term in the medical faculty of the University of Vienna has just been published, and the following items may be mentioned as being of interest. There will be 429 lectures and classes as compared with 416 last summer term, the subjects and the number of classes being as follows: In anatomy and histology, 8 classes, conducted by 3 professors and assistants; in physiology, 13 classes, with 6 professors or lecturers; in medical chemistry, 10 classes, with 3 lecturers; in general pathological anatomy and pathology, 27 classes, with 20 professors and lecturers; in pharmacology, 10 lectures, delivered by 6 teachers; in internal medicine, 98 classes, with 64 teachers; in laryngo-rhinology, 19 classes, with 9 teachers; in pediatrics, 22 classes, with 15 teachers; in surgery, 33 classes, with 24 teachers; in dentistry, 8 classes, with 6 teachers; in otology, 29 classes, with 13 teachers; in ophthalmology, 22 classes, with 11 teachers; in gynæcology, 43 classes, with 26 teachers; in dermatology, 42 classes, with 24 teachers; in psychiatrics, 24 classes, with 18 teachers; and in forensic medicine and hygiene, 17 classes, with 8 teachers. The teachers include 29 ordinary professors, 99 extraordinary professors, and 132 *privat-docenten* and assistants. These classes are meant chiefly for students, but of course they may be attended also by graduates. The above-mentioned programme being an official document, post-graduate work is as a rule not included in it, but is in Vienna conducted more or less on a system of free arrangement. In the last (i.e., the winter) term there were 2818 matriculated students, including 184 women, working in the institutes of the medical faculty. The number of students has increased by 313 over the number in the corresponding term of last year, and the number of female medical students has gone up by 32. As I have already mentioned on a former occasion, the chief increase is produced by the first-year students entering the medical classes in rapidly rising numbers.

Health Statistics for March.

The official report of the Vienna Board of Health for the month of March shows that the public health was excellent, owing to the mild weather, which produced a marked diminution of diseases of the air passages. Scarlet fever alone showed a drop of 50 per cent. and in other infectious diseases there was also a decided change for the better. The mortality decreased by 15 per cent. (2964 deaths against 3378) in comparison with the same period of 1913. Of the deceased 48 per cent. were females and 52 per cent. were males, whilst the infants under one year made up 18 per cent. of all the deaths.

May 4th.

INDIA.

College of Science at Calcutta.

THE foundation-stone of a College of Science in connexion with the Calcutta University was laid recently by Sir Ashutosh Mookerjee, Vice-Chancellor of the University, who in performing the ceremony said that the scheme was first rendered practicable through the execution of a trust deed by Sir Tarak Nath Palit, whereby he transferred money and land valued at more than 7 lakhs for the promotion of pure and applied science among his countrymen. A few weeks later Sir Tarak Nath Palit executed a second deed of a similar amount for the purpose of aiding the trusts mentioned in the first deed. The University Syndicate had received the Government's permission to apply Rs.12,000 annually for the maintenance of the laboratory, and Dr. Rash Behary Ghose had offered 10 lakhs for the foundation of four professorships and eight research studentships.

Calcutta Hospital Nurses' Institution.

The report of the Calcutta Hospital Nurses'

Institution for 1913, just published, shows a loss on the working of the year of Rs.4,081.11.6. The income of the institution is mainly derived from public grants from the Government of Bengal, the corporation of Calcutta, the Hospital Port Dues Fund, and additional fees from the Woodburn Ward of the Presidency General Hospital. During 1913 there was a falling off in the subscriptions from the public and also in the offertories from the churches. The main object of the institution is to train nurses and to provide them free of charge to the leading Calcutta hospitals, about 170 nurses being now employed.

School of Tropical Medicine.

According to the *Englishman* a serious difficulty has arisen over the staffing of the proposed School of Tropical Medicine. The Government wishes to staff it mainly, if not exclusively, with Indian Medical Service officers, while Lieutenant-Colonel Leonard Rogers, I.M.S., desires to engage a staff of experts of established reputation. Colonel Rogers is said to have intimated to the Government that unless the original scheme is adopted he can have nothing to do with the proposed school, and it is believed that he is prepared to resign.

Strike of Bombay Milkmen.

The new by-laws made by the Municipal Commissioner for the purpose of controlling the milk trade of Bombay with the view of supplying the city with pure and unadulterated milk have just come into force. These by-laws require all the owners of dairy farms and milch cattle, milk shopkeepers, hawkers, and servants of dealers in milk who supply milk to the customers at their places to procure licences from the Municipal Commissioner. The by-laws provide for the control and supervision of premises used for keeping milch cattle for sale or hire, or for sale of the produce thereof; also for inspection of such cattle, and for securing the cleanliness of milk stores, milk shops, and milk vessels. Though only nominal fees are charged for licences the owners of about a dozen dairies recently issued a combined notice to their customers intimating that in view of the new by-laws coming into force they had been obliged to raise the price of milk from 3 annas to 3½ annas from April 1st. Disputes between the milkmen and their employers have resulted in the former refusing to deliver milk to the customers, and a large section of the people are being put to no small amount of inconvenience owing to the non-supply of milk.

Sanitation in the Civil Station of Lahore.

A correspondent of the *Civil and Military Gazette* seriously indicts the sanitation of the capital of the Punjab. He says that the sanitary arrangements of the Lahore Civil Station are so defective as to call for the personal intervention of the householder in the interest of his own health and that of the public. There is no daily removal of refuse, but accumulation of filth is permitted for two or even three days; at the end of this time a cart calls usually about 8.30 A.M. Into this cart, which is an ordinary bullock cart, with reed matting sides and without any cover, the contents of the sanitary bins are thrown in a most careless manner. The bins are thus never completely emptied and they are never cleansed. The process of removal, which takes place about breakfast time, is therefore a most offensive proceeding, and the carts themselves being wholly unfitted for such work leave a foul odour and a trail of filth in their path. The writer suggests that the civil station should be wholly or in part removed from the jurisdiction of the Lahore municipal committee and placed in the hands of a committee composed entirely of residents in the civil station. There are probably objections to this proposal, but so far as sanitation is concerned there is much to be said in favour of its adoption.

The Students' Strike at Lahore.

The committee to inquire into the alleged grievances of the students at the Lahore Medical College met on April 5th under the presidency of Surgeon-General Sir Pardey Lukis, I.M.S.

April 14th.

AUSTRALIA.

Melbourne University.

A DEPUTATION from the council of the Melbourne University recently waited upon the Premier of Victoria (Mr. Watt) with a request for increased Government aid to the finances of the institution. It was stated that many of the buildings were in serious disrepair and that the various schools required financial aid to provide for expansion of work. While the Sydney University has handsome private endowments the Melbourne University is practically dependent upon the sympathy of the Government. Upwards of £150,000 was mentioned as necessary to make matters perfectly satisfactory. Mr. Watt replied sympathetically, and promised to make inquiries by sending an architect to report upon the building propositions and to take the other representations into Cabinet consideration.

The Women's Hospital, Melbourne.

At a recent meeting of subscribers to the Women's Hospital, Melbourne, some feeling was manifested. This institution has a midwifery and a gynæcological department. There are four honorary medical appointments to the first and eight to the second, the latter being divided among four indoor surgeons and four assistant surgeons with charge of out-patients. The customary rotation of office has been from the midwifery appointments to the gynæcological. Recently there has been professional unrest among the operating surgeons owing to the demand for one or more beds by the assistant surgeons. As a solution the committee proposed to increase the number of surgeons from four to six in the gynæcological department. This was opposed by a certain number of the existing senior surgeons, and matters promised to be lively at the meeting called for the necessary alteration of the rules. However, the opposition proved to be lacking in determination, and the proposals of the committee were adopted without serious dissension.

Melbourne Hospital.

The Melbourne Hospital until recently had no special departments except that of dermatology. When the new building was opened appointments were made to departments for diseases of the eye and of the throat and nose. It is now announced that a gynæcological department will be opened, and applications have been invited for the position of gynæcologist to the hospital.

St. John Ambulance Association, Melbourne.

Dr. J. W. Springthorpe, in opening the new headquarters of this association at 463, Swanston-street, Melbourne, said they undertook ambulance work in Melbourne in 1908 after other authorities had refused. Last year there were 25,000 calls, and there were now five cars constantly at work. They received no Government grant and only £123 from municipalities. Last year they transported £800 worth of municipal cases. The deficit on the year's work was £476, and a fourth motor ambulance had been ordered, but towards the cost of this several donations had been received. A sum of £250 was still required. The Lord Mayor declared the building open, and said that 15,468 persons in Victoria had received certificates of proficiency in first aid.

Presentation Portrait.

One of the permanent memorials of the jubilee of the Melbourne Medical School, which will be celebrated on April 30th and May 1st, will be a portrait of Professor Sir H. B. Allen, to be hung in the Wilson Hall. The portrait has been completed by Mr. E. Phillips Fox, a well-known Australian painter, and is pronounced to be an excellent likeness. The cost of the picture is being met by a number of graduates of the medical school.

Small-pox in Sydney.

Small-pox has not yet disappeared in New South Wales, and there are at present about 25 cases and a number of contacts at the quarantine station. Cases are also reported from Newcastle. Some inconvenience has been caused by the arrival of the *Orsova* with a case of small-pox from Colombo, and the ship's company have had to be accommodated at the quarantine grounds. The New South Wales Government decline to pay a sum of £6000 claimed by the Federal Government for the use of the quarantine station during the past nine months

The Australasian Medical Congress.

Considerable discussion took place at the final meeting of the recent Australasian Medical Congress in Auckland on a motion recommended by the council of the New Zealand branch of the British Medical Association, viz.: "That membership of future congresses be limited to members of the British Medical Association." The reasons given in support were the overlapping in the work of the two bodies, and the necessity of remitting congress resolutions to the branches of the British Medical Association. The motion was proposed by Dr. W. Young (Wellington), and seconded by Dr. J. R. Purdy (Wellington). It was supported by Dr. R. Worrall (Sydney) and Dr. Sinclair Gillies (Sydney), and opposed by Dr. F. A. Pockley (Sydney), Hon. Dr. Nash (Sydney), and Dr. T. Dixson (Sydney), who argued that the motion, which was brought without notice, if carried would certainly alienate the sympathy of every State Government from future meetings of congress, since there were a number of reputable practitioners who were outside the British Medical Association. An amendment "that future congresses be congresses of the British Medical Association" was carried.

April 23rd.

ROYAL SANITARY INSTITUTE.—A sessional meeting of this Institute will be held at St. Helens on May 22nd, when a discussion will take place on the Hygiene of the Preparation, Storage, and Distribution of Food, to be opened by Dr. H. Joseph Cates, medical officer of health of St. Helens. The following medical men are expected to take part in the discussion:—Mr. T. W. Naylor Barlow, Mr. Joseph Beard, Mr. H. B. Corkin, Dr. W. Allen Daley, Dr. G. W. N. Joseph, Dr. E. W. Rees Jones, Dr. R. Sydney Marsden, Dr. A. B. McMaster, Dr. Stewart Stalker, and Mr. John J. Weaver. The chair will be taken at 7.30 P.M. by Colonel J. Lane Notter, R.A.M.C., treasurer of the Institute.

Correspondence.

"Audi alteram partem."

MONKEYS AS RESERVOIRS FOR THE VIRUS OF YELLOW FEVER.

To the Editor of THE LANCET.

SIR,—Though one cannot deny the possibility brought forward by Dr. Andrew Balfour in THE LANCET of April 25th that wild monkeys may act in certain places as reservoirs for the virus of yellow fever, yet anyone especially knowing the West Indies must at once see that this means is uncommon, if in fact it ever occurs at all. Recently numerous theories, chiefly made by people who have never seen yellow fever or studied the disease in its endemic areas, have been brought forward suggesting that animals may act as intermediate hosts or carriers of the virus. Agramonte and others have criticised this idea rightly, and have shown that as regards Cuba there is nothing to support such a view.

The West Indian Islands are, as a matter of fact, a very good place to study such a question, and during a visit paid to these parts in 1901 I had the good fortune to go through a yellow fever epidemic in St. Lucia, and also made observations upon the subject in the other islands as well. From these it is almost certain that the question of an animal host does not exist. If it did, then the disease would always be existent in those parts, and amongst the constant supply of non-immunes visiting these islands cases of definite yellow fever would always be occurring. Now such is not the case; once the disease is stamped out of the human population the island remains free until some chance importation of a case or of an infected mosquito brings back the virus. Cuba is a case in point; St. Lucia, where I studied the disease, was also so; and Barbados and the other islands also furnish similar examples. Epidemiological researches, then, carried out in suitable areas such as these are against an animal host, and still more strongly so are they against monkeys of any sort, especially red howlers. In most of the West Indian Islands such monkeys do not exist, and one must further remember that the disease occurs, even in places where there are monkeys, practically always in towns where such animals are conspicuous by their absence. The case of the town of Maracaibo, mentioned by Dr. Balfour, is only another example of this well-known fact.

It is right in passing to mention here that there are some monkeys in Barbados, but these live in a semi-preserved condition in a wood miles away from Bridgetown, the chief seaport, and are, I believe, descendants from West African monkeys brought in the old days by the slaves. They are not red howling monkeys, a species inhabiting the forests of Brazil, British Guiana, &c. Further, against the latter monkey being a carrier of the disease is the fact that it abounds, as I have just said, in the woods and forests of British Guiana, where, so far as I know, cases of yellow fever are not met with amongst the non-immunes who traverse these areas. Whilst travelling there in 1901 and investigating the filariasis which is found amongst the aboriginal Indians I had ample proofs of observing the diseases of the country and I never met with yellow fever myself or heard of anyone else having seen it there. When yellow fever has been met with in British Guiana it has occurred in Georgetown, the chief seaport, or in the other towns of the coast line.

Referring to Dr. Balfour's paper again, I cannot say that the question of importation from the mainland is negatived in the recent small outbreak of yellow fever at Brighton, near the pitch lake in the south-west of Trinidad, nor can I agree with the remarks attributed to Mr. George—namely, "There is not the slightest evidence that the disease was conveyed here from outside sources." Dr. Balfour expressly states that Case 1, an American, had only been five days in Trinidad, and he had arrived there from the *Venezuelan mainland five days before being struck down*. It is perfectly clear to my mind, therefore, that he either acquired the disease on the Venezuelan mainland or on his transit from there to Trinidad. Case 2, who was taken ill almost at the same time as Case 1, is not perhaps so easy to explain as he had not been out of Trinidad for one year and seven months.

There is no doubt that sporadic cases, of what appears at least to be yellow fever, have cropped up from time to time in endemic yellow fever areas. That all of these have been genuine cases one cannot say definitely, because in many instances no necropsies have been performed nor any careful examinations made. In the light of recent research and improved diagnosis it will be interesting to see if such cases still occur.

The finding of bodies, similar to those described by Scott Macfie and Johnston in guinea-pigs and dogs, in monkeys' blood would be interesting, but would mean nothing. It has yet to be proved that these bodies are parasites, and, secondly, even if they are that they have anything to do with the cause of yellow fever. Recently looking at guinea-pigs' blood with Dr. C. M. Wenyon here in England we have seen bodies very similar to those described by the two observers just mentioned. Before their results can be accepted, therefore, confirmation must be forthcoming. I do not propose to enter into the controversy of Seidelin's bodies here at this moment. Agramonte, Schilling, Guiteras, and others, all very competent observers, have already done so, and their opinion is certainly against them.—I am, Sir, yours faithfully,

GEORGE C. LOW, M.A., M.D.,
Lecturer, London School of Tropical Medicine.
Bentinck-street, W., May 1st, 1914.

THE INFECTIVITY OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In the annotation in your issue of May 2nd on certain evidence presented in regard to the methods of spread of tuberculosis, you state that "phthisiophobia is to be strongly deprecated," and such an expression of opinion from so weighty a journal as THE LANCET is of high value at the present time.

But I would ask to be allowed to draw the attention of your readers to the valueless nature of the evidence on which the conclusions are drawn by Dr. Lampson, to the effect that "the spread of tuberculosis in families having open cases of tuberculosis is greater than is generally believed." The spread of infection is considered in families, or those living in the house with them. Of such persons, the greater number would probably be members of the same family. The researches of Pearson and Goring have suggested that the heredity figure for phthisis is definite and fairly high. Hence full correction must be made for this factor before it is fair to begin to estimate the possible effects of infection. So far as stated, no such correction is made, and hence the deductions drawn are bound to be misleading. So far the most definite evidence on the point is the results of the various inquiries which have been made into the spread of infection among non-related persons in sanatoriums, and such inquiries have shown that "adults are very little endangered by close contact with open tuberculosis."

Apologising for troubling you with the matter,
I am, Sir, yours faithfully,
Colwall, Malvern, May 2nd, 1914. MARY H. WILLIAMS.

To the Editor of THE LANCET.

SIR,—In your annotation in THE LANCET of May 2nd you give an account of the view of Dr. Baldwin, of Saranac Lake, that the risk of infection of adults from cases of open pulmonary tuberculosis is small, and of the observations of Dr. Lampson, of Minneapolis, who found that an excessively high proportion of other members of the family reacted to tuberculin if one member of the family suffered from open pulmonary tuberculosis.

I am led to ask, Might not Dr. Baldwin reply that this excess might be due to abnormal susceptibility of these families to tuberculosis infection generally, of which the occurrence of a case of open pulmonary tuberculosis was indication, and not necessarily to infection derived from this case? I confess I am interested in the question from the point of view of the evidence upon which we must rely in this matter. I am, Sir, yours faithfully,
May 2nd, 1914. STUDENT.

THE FATALITY OF MEASLES.

To the Editor of THE LANCET.

SIR,—Anything connected with measles is important to the clinician and health officer, for measles and whooping-cough are the two most deadly and destructive diseases which menace the life and after well-being of the young child. I fear them more than either diphtheria or scarlet fever, of which the general public have such a dread, just as they regard measles and whooping-cough so light-heartedly. I wish both latter diseases were notifiable, for I am sure this would lead to a saving of young lives, but authorities are penny wise and pound foolish.

In three recent epidemics I have complete notes of 200 cases, of which 75 per cent. were in children of 5 or under, and a like percentage of the cases belonged to the artisan class. The deaths were six, equal to 3 per cent. All died of broncho-pneumonia, and one was aged 2 and the other five were 18 months or under. Of the 200 only two suffered from middle-ear disease, or 1 per cent., and one of the cases dried up completely at the end of 10 days and without impairment of hearing. Four of the 200 cases, aged respectively 6, 3, 2, and 1½ years, had "running ears" before, and they are not included. The low percentage of middle-ear disease seems to me worthy of special note, and I believe this happy result as well as the low death-rate is due to our better management of cases of measles during the last 20 years.

My own plan is to allow nothing but cold water, aerated water, lemonade, or weak tea for the first

48 hours after the rash appears. This helps to keep the mouth, pharynx, and naso-pharynx sweet and clean, and as no solid food is given putrefaction is largely prevented, and so there is less danger of mischief spreading along the Eustachian tube. I insist on the children sleeping between sheets and that the patients be sponged down all over twice a day at least, and that they be kept cool and not have their beds right up against a roaring fire, as was so common a practice in former days. I think a fire in the bedroom is useful, for it sometimes relieves a troublesome cough, but I insist on open windows but avoidance of draughts. I ask the mother or nurse to flush the room thoroughly with fresh air twice a day at least. I tell them that the irritating cough is not due to "cold," but is the result of the poison of the measles; that it will disappear as the poison is got rid of, and that the best channels of elimination are the skin and the kidneys. This note of explanation generally sets their minds at rest as to fresh air. I tell the attendants to keep the mouth clean and to attend to any discharge from the eyes and nose by washing with water that has been boiled and allowed to become lukewarm, and I point out the advantage of using small pieces of absorbent cotton wool or clean rag, which should be used only once and then burnt. I prescribe a mixture of ipecacuanha wine and solution of ammonium acetate and syrup, which is useful and comforting, and if there is great restlessness or if the cough is very troublesome I add thereto potassium bromide and morphine hydrochloride in suitable doses.

I am, Sir, yours faithfully,
J. GORDON SHARP, M.D. Edin.
Leeds, May 4th, 1914.

THE PAYMENT OF FEMALE MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—You courteously granted me space for a letter on the above subject in your last issue in regard to the salaries of inspectors of the mentally deficient. It is gratifying to know that the second candidate has now sent in her resignation to the Board of Control.—I am, Sir, yours faithfully,

JANE H. WALKER,
President of the Registered Medical Women's Association.
Harley-street, W., May 4th, 1914.

TRAUMATIC DISLOCATION OF THE HIP-JOINT.

To the Editor of THE LANCET.

SIR,—The two cases of this accident recently reported in THE LANCET (April 18th and May 2nd) remind me that on Nov. 20th, 1911, I had a similar case in a boy in his eighth year. I do not know his exact age, but in the dispensary ticket issued to me his age was set down as 7 years. When the accident happened he was sitting in a cart drawn by a donkey. In turning a corner one wheel went up on the bank and the cart was overturned on the boy. When I saw him a few hours later I found a typical dislocation of the head of the left femur on to the dorsum ilii, the attitude of the limb exactly resembling the conventional diagram in the books. I gave the boy chloroform, and got his father to make steady traction in the direction of the limb. Of course I had no skilled assistance. With a little manœuvring and manipulation reduction was readily brought about. No splint was applied. The legs were bandaged together. There was no other injury and the boy was able to walk in a week. In the case reported on April 18th the patient "was allowed to put weight on the limb on the twenty-eighth day." That seems to have been pathetically timid. I am, Sir, yours faithfully,

J. F. KEENAN, M.B.
Ballinalee, Edgeworthstown, May 5th, 1914.

OVER-CONSCIENTIOUSNESS IN WOMEN.

To the Editor of THE LANCET.

SIR,—One very important feature in the work of women is brought to notice by the closing remarks in the third section of your Special Commissioner's article upon panel practice in Stepney and Enfield, published on April 25th. The quality of over-conscientiousness greatly mars the future prospects of many young women. Prosperity and promotion, instead of bringing greater ease, more comfort, and a healthier home life, often result in a complete collapse. Women are apt to allow their business to take too great a hold of them. They feel the anxieties, the difficulties, above all the responsibilities, too keenly. So long as they remain shop assistants or occupy some other subordinate position they continue to work and their strength and health hold out. But when they are promoted to a responsible position as manageress of a shop or a department, then they take to heart so keenly the various incidents, especially the unpleasant incidents, of their business that health gives way as a consequence of their hypersensitiveness or over-conscientiousness. Panel doctors are, I am sure, already in a position to testify to this very important and significant fact.

I was speaking recently to a lady who has been an ardent worker for the Band of Hope during now more than 20 years, and has, therefore, had time to follow up the careers of some of the girls who have been under her charge. This lady at once mentioned the case of one of her old pupils who used to earn her living very successfully and for several years as assistant at a fashionable London pastry-cook's shop. But the business was so prosperous that the owners opened another shop not far off and appointed the assistant in question as manageress. This should have meant better health and more wealth; it proved just the contrary. The strain, anxiety, and responsibility were too great. The new manageress soon became a hopeless invalid and had to give up work altogether.

Another of these Band of Hope girls worked for several years as waitress at one of the A.B.C. tea-rooms; but when finally she was appointed manageress she also broke down and has now been for two years incapable of doing any work whatsoever. Then a third case—in a small sweetstuff shop in South London one of the Band of Hope girls was engaged to assist the manageress for a wage of 10s. a week. So long as the work continued on this modest basis all went well. But one day the manageress elected to leave the business, and the owner of the shop thought the assistant was not only experienced enough to be appointed manageress in her turn but was young and energetic enough to attend to the whole business herself without anyone to help her. The anxiety and responsibility destroyed her health, and anæmia and nervous prostration incapacitated her for any work whatsoever.

The greater amount of medical care which, in response to the National Insurance Act, is now bestowed on women workers will help to throw light on their special weaknesses and their special requirements.—I am, Sir, yours faithfully,

April 27th, 1914. PRACTICAL.

"THE MENACE OF CANCER" AND AMERICAN VITAL STATISTICS.

To the Editor of THE LANCET.

SIR,—In regard to the discussion on the trustworthiness of American vital statistics, Dr. Horst Oertel takes adequate care of himself in THE LANCET of April 18th against the depreciatory statement by Mr. Frederick Hoffman in THE LANCET of April 11th, that "the views of Oertel [as to the "*greatest laxity and inaccuracy*" which obtains in New York City] have not been accepted by qualified critics, although justified to a limited extent as regards initial diagnosis in hospital practice." Mr. Hoffman does not state what, in his judgment, constitutes a qualified critic, or whether he means that no qualified critics have accepted Oertel's views, or only that some have not. However, there has just come to hand information which seems to show that some critics undoubtedly support Dr. Oertel; whether these critics would be regarded by Mr. Hoffman as "qualified" he alone can say.

The information is contained in a cutting from the *Evening Post* of New York for March 30th, one of the most weighty of American newspapers, on account of its usual trustworthiness in regard to facts, the judicial character of its opinions, and its comparative restraint of expression. From this cutting it will be seen that the Hospitals Investigation Committee appointed by the Board of Estimate of New York City, after an exhaustive study of the number of necropsies performed in Bellevue and Allied Hospitals, and of *mistakes made in diagnoses* and in clinical examinations, recommend that the State law as to necropsies be changed so as to enable hospitals to perform a much larger percentage of necropsies than at present. Dr. Oertel's figures are quoted to establish the fact that of the 482 cases that came to necropsy, in 47·7 per cent., or close on one-half, the necropsy findings did not confirm the clinical diagnosis. If this percentage can be extended to the total of 3170 deaths, which according to Dr. Oertel's figures took place in one year in Bellevue Hospital, it would indicate 1521 deaths from conditions unknown or incorrectly diagnosed. The report further points out that at Bellevue necropsies are performed on only about 10 per cent. of those dying in hospital, as against 84 per cent. at University College Hospital, London, 99·9 per cent. at the Allgemeines Krankenhaus, Vienna, and 90 per cent. at most of the German hospitals. Every opportunity for post-mortem examination is afforded by Bellevue, which incorporates in its pathological buildings a morgue capable of accommodating 225 bodies, four necropsy rooms, and undertakers' rooms, but it is exceedingly difficult to secure permission for necropsies from relatives and friends, while in the case of unclaimed bodies the existing law, as interpreted by the late Commissioner of Charities, forbade necropsies thereon, and ordered them to be distributed intact among the medical colleges. The new law now proposed by the committee recommends that accredited hospitals shall be allowed to perform necropsies in cases where no objection is made within 48 hours by the next of kin. It seems obvious from the foregoing that there are certainly some presumably qualified critics who not only have accepted Dr. Oertel's views, but even propose to found legislation upon them. An interesting confirmatory case appears in the *Weekly Bulletin of Department of Health, City of New York*, for April 11th, which shows how unsafe are arguments for or against any given theory or principle which are based on clinical diagnosis alone. (And this is the point of the contention, for the medical profession in America has no special monopoly of such errors.) A member of the National Guard died from typhoid fever (so it was certified) on March 30th, 1914, in spite of the fact that he had been inoculated with antityphoid vaccine in January. Indeed, it was alleged that the inoculation not only had failed to prevent the disease, but had actually given rise to the infection. Naturally great commotion was caused, so that a necropsy by the coroner's physicians was held, when it was conclusively shown that there was no evidence of typhoid fever, but that the patient had died from malignant endocarditis and general sepsis.

I am, Sir, yours faithfully,

April 30th, 1914. ANGLO-AMERICAN.

THE NATIONAL INSURANCE ACT.

THE NATIONAL INSURANCE ACT AND THE BUDGET.

THE Budget statement of the Chancellor of the Exchequer contained indications of the directions in which he was prepared to extend financial support to the working of the National Insurance Act. The working of the Act having revealed, as all our readers know, an amount of disease among women which was unexpected, the Government will make a substantial grant to societies whose resources have been depleted as a result, the danger of malingering being guarded against. It is proposed to establish a system of medical referees "who will not merely be a check on malingering but will be a class of doctor whom the societies can call in to decide whether a case is doubtful or not, and who will be consultants." Such are Mr. Lloyd George's words, and it is clear that the officers whom he has in his mind will have very delicate duties to perform, and that the opportunities for friction will be numerous. It is proposed to establish clinics at convenient centres for the assistance of the practitioners on the panels in difficult cases where coöperation is useful, and also to organise a system of health lectures. A certain amount of encouragement is also promised to deposit contributors, whose numbers appear to be falling.

THE GLAMORGAN INSURANCE COMMITTEE AND A QUESTION OF POWERS.

At a recent meeting of the Glamorgan Insurance Committee an important question was raised by a letter from Dr. Marcus S. Paterson, the medical director of the Welsh Memorial, who had written to say that bacilli of tuberculosis had been found in the sputum of a certain man who was living in a house with young children, the local medical practitioner reporting that the conditions of the house were not suitable for the treatment of the disease. The man, however, continued to live in the house and apparently refused to leave it. The chairman of the committee expressed the view that the Insurance Act was defective in providing no machinery for enabling any compulsory steps in such matters, and it was suggested that it was for the Approved Society to take steps. The difficulty and hardship of compulsorily separating a parent from his children was also referred to, and the matter was eventually left to the Sanatorium Benefit Subcommittee to deal with. At the same meeting discussion took place with regard to the prevalence of malingering, and the appointment of medical referees to deal with it was advocated. The question was referred to the Medical Benefit Subcommittee for its consideration.

Panel Doctors with Small Lists.

A meeting of panel doctors with small lists will be held at 3 P.M. to-day, Saturday, May 9th, at the Eustace Miles Restaurant, Chandos-street, Charing Cross, W.C., to hear the report of the committee formed by them on March 17th last. A statement will also be made concerning the interview of the committee with the Panel Service Subcommittee. It is hoped that all directly interested will endeavour to be present.

National Health Insurance and the Irish Corporations.

The Royal College of Physicians of Ireland and the Apothecaries' Hall of Ireland have recorded their regret that in Section 44 (2) of the National Health Insurance (Medical Benefit) Regulations, 1913, and the Memorandum issued in connexion therewith, provision is made whereby insured persons who make their own arrangements for medical benefit under Section 15 (3) of the National Insurance Act may obtain treatment from unqualified persons. The College and the Hall add their regret that under an Act professing to promote the health of the nation unqualified practice should be possible. A similar resolution by the Royal College of Surgeons in Ireland was published last week.

Coördination of Tuberculosis Treatment.

The London Insurance Committee has adopted a number of rules designed to meet the circumstance that in a large number of cases the treatment provided at tuberculosis dispensaries, for which payment is claimed by the dispensary authorities, is such as could be given by practitioners on the panel to whom payment has already been made. The difficulty is that a large number of insured persons have been in the habit of attending dispensaries without a recommendation from the panel practitioner or the Insurance Committee, and frequently without the knowledge of the practitioner. The Insurance Committee has now decided to make it a condition of grants to dispensaries that insured persons treated there must have been referred by the panel practitioner or the Insurance Committee. Practitioners with whom insured persons contract out will act in this matter through the Insurance Committee. The committee has endorsed the view of the Panel Committee that the duties of the practitioner in respect of domiciliary treatment shall be those included in the Local Government Board Order of July, 1912, that the services of the dispensary shall be primarily of a consultative character, and given in coöperation with the practitioner. They shall consist of the more elaborate methods of diagnosis and such treatment (if any) as may be agreed upon between the practitioner and the consulting officer of the dispensary. The committee will require dispensary authorities to make definite arrangements for linking up the panel to the dispensary service and to consider as to giving panel practitioners representation upon dispensary committees. In order to arrive at a basis of grants to dispensaries the proportion of cases referred by practitioners is to be recorded, and the Insurance Committee will institute inquiries in any districts where the proportion is found to be above the average.

The Position of Panel Chemists at Aberdeen.

At a largely attended meeting of Aberdeen chemists the following resolution was passed for transference to the Local Health Committee:—

> That this meeting, having had under consideration the payment of the drug accounts under the National Health Insurance in the Aberdeen burgh area, desire to enter an emphatic protest regarding the inadequacy of the sums paid for the last two quarters, and particularly for the quarter just closed, they only having received 52½ per cent. of the total accounts due; and they also desire to point out to the Insurance Committee that chemists are in no way responsible for the quantity of medicines used, their duty under their contract with the committee being entirely confined to the dispensing of medicines ordered by the medical practitioners on the panel in accordance with the tariff prices agreed upon, and this they claim to have faithfully done. They feel they need scarcely point out to the committee the utter impossibility of such a state of matters being allowed to continue without very serious consequences following. They therefore request the committee to get an assurance from the Commissioners before June 1st that the arrears will be paid within a reasonable time, otherwise they consider the panel system in the Aberdeen burgh area will be seriously imperilled.

It was also agreed that it be remitted to the Pharmaceutical Statutory Committee to send a memorial to the Scottish Insurance Commissioners on the grounds of the following motion:—

> This meeting of panel chemists in the Aberdeen burgh area, in view of the extreme gravity of the position in which they are placed through the inadequacy of payments, hereby require the Statutory Committee to forward to the Scottish Commissioners a memorial setting forth a full statement of the case, assuring them of the impossibility of continuing on the panel under the existing conditions, and request an assurance that in future no *pro rata* arrangement of payment will exist, and not more than 10 per cent. deductions made previous to the checking of the accounts, and that only until the accounts are checked and adjusted; and also protesting against the injustice of paying bonuses in some areas while in others the ordinary accounts are not met.

Scottish Rechabites and Insurance.

At the annual meeting of the Scottish Provincial Council of the Independent Order of Rechabites prominence was given in a speech by Brother Lunan to the question of excessive sickness and to the alleged negligence or want of independence on the part of medical men as being responsible for the drain upon the funds of the societies. The speaker attributed the evil to the fact that medical men were no longer under the control of the societies and were afraid to tell their insured patients that they were capable of work owing to the possibility of their transferring themselves elsewhere. He said that "if the doctors wished to avoid the establishment of a State Medical Service they would best consult their own interests if they acted what he would call honestly." This observation was received with applause. Brother Lunan had already expressed the belief that the majority of the medical profession was acting honestly in the matter of giving certificates, and we may record here the opinion that the honest majority is a great deal larger than he supposes. It may also be suggested that the medical profession is not likely to give up the freedom from the control of Friendly Societies which it now enjoys, and that whatever reasons there may be for advocating the establishment of a State Service, there is nothing to show that its members would be less independent of the societies than they are now. The giving of certificates not demanded by the patient's condition is alleged to be due to a desire to retain insured patients, but it has not yet been proved either that such undeserved certificates are given in large numbers, or that, if so given, they are due to the cause mentioned. Consequently, under a State Service societies might well find themselves no better off than they are now.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the recent Examination in Sanitary Science the following candidates were successful:—

Charles Henry Arthur Alderton, *John Horatio Baldwin, Howell Wood Barnes, *Edward Hamilton Black, David Sands Brough, †Muriel Constance Bywaters, James Cairns, Milton Carrasco, John Marcus Hobson Conway (Captain R.A.M.C.), Lucy Davis Cripps, George da Silva, †Henry Leatham Grabham, William Cooper Gunn, James Stewart Hall, Hiranath Dhondnath Khote, William Maxwell McKie, Hugh McLean, *Malcolm Manson, Felix Oswald Newton Mell (Major I.M.S.), John Morison (Captain I.M.S.), John Carmel Noronha, John Harold Peck, Arthur Errington Rayner, William Bramwell Reid, Eric Hemingway Shaw, James Johnson Sinclair, *Edwin Charles Allan Smith, Norman Walmsley Steinberg, Alfred Maurice Thomson, and Edward Archibald Walker.

* Distinguished in the practical applications of sanitary science and pathology. † Distinguished in the principles of hygiene.

The following medical degrees have been conferred:—

M.D.—L. B. C. Trotter, Clare.
M.B., B.C.—C. R. Taylor, Caius.
M.B.—J. P. H. Davies, Jesus.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW AND ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH.—The recent examinations of the Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, were concluded on April 25th. The following candidates passed the First Professional Examination:—

Reginald Douglas Howat, East Kilbride; Cuthbert Gaulter Macgee, Fleetwood; and Allan Paul McLeod, Barrhead.

The following candidates passed the Second Professional Examination:—

William Brown, Larkhall; John Archibald Steele Campbell, Dalry, Ayrshire; William O'Gorman Donoghue, Glasgow; John Alfred Alexander Duncan, Middlesbrough; Peter Fraser Fairley, Hamilton; Alfred David Gorman, Methven; George Alexander Grandsoult, British Guiana; Percy Hayes, Cork; Harold Cranwell Aloysius Haynes, Victoria, Australia; John William Irvine, Shetland; Edward Glyn Jones, Liverpool; Mary Gray Jones, Motherwell; Alexander Morrison, Glasgow; John Joseph Mulvey, Airdrie; and John Alexander Murray, Glasgow.

The following candidates passed the Third Professional Examination:—

Oswald Brunlees, Roehampton; John Crawford (with distinction), Paisley; David Andrew Imrie, Glasgow; Percy Milnes, Brighouse; George London Neil, Lesmahagow; John Mellon Smeaton, Glasgow; Frederick William Thompson, Garlieston; and William John Mitchell White, Glasgow.

The following candidates passed the Final Examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.R.F.P.S.G.:—

William MacLeod, Glasgow; Edward Dias, Goa; Jerome Suares, India; John Corcoran, Cork; Gopal Das Madhok, India; Violet Millicent Tracey, Glasgow; William James Valentine Curtain, Melbourne; Muljibhai Kuberdas Dalal, Bombay; Fred Miller Murray, Glasgow; Maud Bennett, London; and Léon Galdemar, Mauritius.

CHELSEA TUBERCULIN DISPENSARY.—Owing to the death of the Duke of Argyll the ceremony of opening this tuberculin dispensary is postponed from to-day (Saturday, May 9th) to Friday, June 5th, at noon, when H.R.H. Princess Christian of Schleswig-Holstein has again consented to attend and perform the ceremony. The dispensary will be open for inspection on Saturday, June 6th, from 2 to 6 P.M.; tea at 4.30.

UNIVERSITY COLLEGE, LONDON.—The Page-May memorial lectures for the current session will be delivered by Dr. Keith Lucas, F.R.S., Trinity College, Cambridge, on the Conduction of the Nervous Impulse. The course will be held at University College on Fridays at 5 P.M., beginning on May 15th. The lectures are open to all internal students of the University of London, and to such other persons as are specially admitted. Applications should be addressed to the secretary, University College, Gower-street, London, W.C.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on April 29th, Sir Francis H. Champneys being in the chair. A number of midwives were struck off the roll, the following charges amongst others having been brought forward: The child suffering from inflammation of and discharge from the eyes the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E.20 (5); not keeping the register of cases as required by Rule E.23; disregarding the wish of the patient's relatives for medical assistance; neglect to take the pulse or temperature of the patient at visits; douching the patient with an unsuitable appliance; neglect to notify the local supervising authority when medical aid has been sought, as required by Rule E.21 (1); not keeping the bag of appliances in a cleanly condition; being unable to use a clinical thermometer with accuracy, and consequently unable to comply with Rule E.13. Medical aid having been sought for the patient on the day of the confinement the midwife neglected for some days to notify the local supervising authority thereof, as required by Rule E.21 (1); and not keeping the register of cases as required by Rule E.23.—A meeting was held at Caxton House on April 30th, Sir Francis Champneys being in the chair. Letters were considered from the Local Government Board with reference to the chairman's letter of Feb. 20th criticising the provisions of the Ophthalmia Neonatorum Order, 1914, and from the medical officer of health of Manchester on the same subject. The Board directed: (*a*) that the Local Government Board be thanked for their letter; (*b*) that the medical officer of health of Manchester be thanked for a copy of his circular on ophthalmia neonatorum. A letter was considered from the London County Council asking whether the Board is prepared to issue instructions with regard to the most effective germicide to be used by midwives for the treatment of the eyes of infants during the first few days after birth. The Board decided that the reply be that the principle of the Board has been to refrain from ordering any special drug in such cases as are therein referred to inasmuch as opinions differ, and it would, in their view, be unwise to frame a rule ordering the use of any particular germicide inasmuch as the breach of such a rule could not rationally be punished if the delinquent were able to quote recognised authority for the use of the particular germicide—other than that authorised by the Board—used by her. A letter was considered from the honorary secretary of the Southampton Midwives Association asking whether Credé's method may be used by a midwife as a preventative in cases of ophthalmia neonatorum. The Board directed that the reply be: (*a*) that the Board has purposely refrained from issuing orders on points of treatment on which recognised authorities differ; and (*b*) that the Board has never ordered the use of Credé's method as a prophylactic. A letter was considered from the medical officer of health of Carlisle inquiring as to what is to be regarded as a stillbirth for the purpose of the Notification of Births Act, 1907. The Board decided that the reply be that the Board points out that it has no specific functions with regard to carrying out the Notification of Births Act, 1907. That as regards the duties of a midwife in notifying stillbirths to the local supervising authority the definition of a stillbirth is given in Rules E. 21 (1) (c) note as follows: "A child is deemed to be stillborn when after being completely born it has not breathed or shown any sign of life." A letter was considered from the Infantile Health Central Committee forwarding a copy of a resolution passed at a meeting held on April 28th suggesting that the Board should include the subject of the hygiene of infant clothing among those upon which candidates for the Central Midwives Board's certificate are liable to be examined. The Board directed that the Infantile Health Central Committee be informed that candidates for the certificate of the Central Midwives Board are already liable to be examined on the subject specified (Rules O.4 (n)).

CENTENARY OF THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.—The medical staff of the Royal Hospital for Diseases of the Chest are celebrating the 100th anniversary of the hospital by a commemoration dinner, to be held at the Savoy Hotel to-day (Friday, May 8th). This hospital makes the honourable claim to be the first established in Europe for the special treatment of thoracic disease, including pulmonary tuberculosis.

UNIVERSITY OF LEEDS: FACULTY OF MEDICINE.—The following special lectures on medical subjects will be given in the Great Hall of the University at 4 P.M. on Wednesdays:—Rheumatoid Arthritis and Allied Conditions, Mr. T. S. P. Strangeways, director of the Cambridge Research Hospital, May 13th; Lead Poisoning from the Industrial and Medical Point of View, Sir *Thomas* Oliver, professor of medicine in the University of Durham, May 20th; Intestinal Stasis, Sir W. Arbuthnot Lane, senior surgeon, Guy's Hospital, May 27th. Admission will be free to members of the medical profession on presentation of their visiting cards.

COMMITTEE ON "SPIRITUAL HEALING."—As the result of a conference of representatives of the clerical and medical professions held in the Chapter House of St. Paul's Cathedral in October, 1910, a standing committee consisting of 9 clergymen and 11 medical men, with Bishop Ryle, Dean of Westminster, as chairman, was appointed to investigate "spiritual," "faith," and "mental" healing, to safeguard against their dangers, and to promote coöperation between the two professions. The medical members were Sir Dyce Duckworth (vice-chairman), Dr. Stanley Bousfield, Dr. Charles Buttar, Mr. W. McAdam Eccles, Dr. F. de Havilland Hall, Dr. Theo. B. Hyslop, Dr. H. G. Gordon Mackenzie, Dr. J. A. Ormerod, Sir R. Douglas Powell, Dr. Howard H. Tooth, and Sir T. Clifford Allbutt. According to its report just published by Messrs. Macmillan the committee held 19 sittings and investigated a considerable number of cases of alleged healing, in the greater number of which, however, no medical evidence was obtainable. Attention was particularly directed to the investigation of cases of ordinarily incurable diseases, but in no such disease as, for instance, cancer, Raynaud's disease, or disseminated sclerosis did it appear that the course of the actual disease had been in any way retarded. A digest of those cases in which it was possible to obtain medical evidence both before and after treatment is given in Appendix B, and in Appendix C is a summary of the evidence of some of the witnesses. The conclusions arrived at by the committee, all of whom sign the report, are that so far as they have a purely medical aspect the physical results of what is called "faith" or "spiritual" healing do not prove on investigation to be different from those of mental healing or healing by suggestion; they recognise that suggestion is more effectively exercised by some persons than by others; they consider that as in all treatment by suggestion spiritual healing can be expected to be permanently effective only in what are understood as functional disorders, and that alleged exceptions are too disputable to be taken into account; and they emphasise this point to warn those who resort to "healers" of the dangers of postponing medical treatment. They consider spiritual ministration should be recognised equally with medical ministration for the sick. The committee propose to continue their investigations, and will be glad to have cases of spiritual healing brought to their notice that comply with the following conditions: (1) a diagnosis by a medical practitioner before treatment, with a short history of signs and symptoms; (2) an account of the treatment, with dates and details; (3) a medical examination, by the same doctor if possible, after treatment, with a detailed account of the changes that have taken place.

UNIVERSITY COLLEGE, READING.—A new gymnasium which has been presented to University College, Reading, by Dr. and Mrs. J. B. Hurry, has just been opened.

LITERARY INTELLIGENCE.—Mr. Henry Kimpton announces the publication of a new work on the "Eye, Nose, Throat, and Ear: A Manual for Students and Practitioners," by James Forrest, M.B., Ch.B. Edin.; also a new seventh edition of "Consumption, a Curable and Preventable Disease," by Lawrence F. Flick, M.D. Philadelphia.

LIVINGSTONE COLLEGE: APPOINTMENT OF A NEW PRINCIPAL.—The committee of Livingstone College have decided to appoint the vice-principal, Dr. Loftus E. Wigram, formerly honorary secretary of the Church Missionary Society, to succeed Dr. Charles F. Harford as principal of Livingstone College, when the latter resigns his post at the end of July.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Milk and Dairies (Scotland) Bill.

Mr. MCKINNON WOOD, the Secretary for Scotland, has introduced a Bill "to ensure the purity of milk-supplies and to regulate dairies in Scotland, and for other purposes connected therewith." It has been read a first time.

The Medical Profession and the Income-tax.

Some members of the medical profession will be affected by the new income-tax proposals put forward by Mr. LLOYD GEORGE in his Budget statement on Monday, May 4th. For earned incomes under £1000 the present rate of 9*d.* in the £ is continued. In the case of incomes from £1000 to £1500 the present rate of 9*d.* is increased to 10½*d.* Incomes from £1500 to £2000, which formerly paid at the rate of 9*d.*, will in the future pay at the rate of 1*s.* The present rate on incomes from £2000 to £2500 is 1*s.*, but it is to be raised to 1*s.* 2*d.* Incomes ranging from £2500 to £3000 are now taxed at 1*s.*, but the future rate will be 1*s.* 4*d.* Incomes over £3000, which now contribute at the rate of 1*s.* 2*d.* in the £, are to be taxed at 1*s.* 4*d.* In addition to these increases of the rate in the case of earned incomes, the tax on unearned incomes is to raised from 1*s.* 2*d.* to 1*s.* 4*d.* in the £. The super-tax limit is lowered from £5000 to £3000, and there again the principle of graduation will take effect.

The Budget and Public Health.

Mr. LLOYD GEORGE in the course of his Budget statement made reference to public health and national efficiency, and also to the necessity for Government assistance to National Insurance. Under this head he made important proposals as to medical referees and clinics. He said that there was no more important branch of the public service than that which dealt with the prevention and the cure of disease. Much of the disease and lack of vitality might be due to the faults and weaknesses of people, but there was a great margin which was due to other causes—causes which were entrusted to the supervision, care, and control of the local authorities. For instance, there were the unhealthy and overcrowded dwellings which were such a prolific source of depressed vitality in this country. There were the absence of sufficient provision for the cure of disease in its initial stages, the absence of any systematic instruction in the principles of health, and the lack of the supervision in the nurture and upbringing of children. He would like to say a word about the stamping out of tuberculosis, the most terrible plague that ever afflicted any country. Some municipalities had dealt with this problem with great public spirit. Notably that was so in the case of Liverpool and Birmingham, and some county councils in England, Scotland, and Wales had shown the same spirit. He wished he could say the same thing of the municipality that ought to lead the cities of the Empire for bettering the conditions of its working people—he meant London. For reasons which he could probe, but which he did not intend to dwell upon, the authority there had been dilatory, suspicious, obstructive, laggard in the attempt to stamp out tuberculosis. There was some excuse to be found in rates. He proposed that in future local authorities should be pressed to show greater activity and enterprise in grappling with all these evils that were sapping the national health and happiness. Parliament was on the eve of proposing great changes to deal with the housing problem. The first thing was to put local authorities in a position to enable them to carry out these proposals without being crippled and handicapped by rates. The contribution which the Government proposed to make to the rates would be used as a means of pressing local authorities to deal with more spirit and boldness with such matters as housing, including the clearing of slums and a provision of better accommodation, the provision of a sufficient number of hospitals, and the grappling with greater energy with tuberculosis. The total grant for the United Kingdom would be £4,000,000 for the first full year. There were certain services which required such immediate action and stimulus that he proposed specific and separate grants with respect to them. They were in the region of coöperation between insurance and local government. The first was the campaign against tuberculosis. While the Insurance Act was passing through the House of Commons a provision was inserted extending the tuberculosis arrangements to dependents of insured persons. It was contemplated that the local authorities should bear half the deficiency and the Government should provide the other half. A good many local authorities had undertaken the work, and there was a considerable sum this year in the estimates for the Government half of that expenditure. Now that the public health grant was to be made, and a substantial grant, on the condition of efficient discharge of the duties of the localities in respect of public health, more money would be required. Where the local authorities were not ready to take up the work the grant would be made to the Insurance Committee, so that the dependents of insured persons should not suffer through the slackness of any local authority. There would be considerable grants for that purpose. There was another branch of the service which was also in that region between insurance and local government. The Insurance Act had helped to make it clear that any system of doctoring was hopelessly inefficient which was not supplemented by a good system of nursing. There were voluntary associations throughout the country doing admirable work, but they were inadequately financed. The local authorities of some districts were also doing this work. The Government proposed to provide a substantial annual sum to help the work of providing and training an adequate supply of nurses. There was another deficiency which had been exposed by the operation of the Insurance Act. There was no provision for the scientific diagnosis of disease. In Germany, in almost every town, and he thought also in France, there were pathological laboratories which were of enormous assistance to medical men in ascertaining the real character of a disease when they were in doubt upon the subject. There were a few boroughs in the United Kingdom where something had been done, even in London, but the Government proposed to make a grant for the purpose of aiding the local authorities to set up these laboratories throughout the United Kingdom. The total of these three services would be £750,000.

Mr. AUSTEN CHAMBERLAIN: Is that additional to the £4,000,000 for public health of which the right honourable gentleman spoke?

Mr. LLOYD GEORGE: Yes; these are specific services for which we are going to give special subsidies. The right honourable gentleman went on to discuss educational problems, including the feeding of necessitous school children. There were still 260,000 children who needed but received no relief at all, and many others who received inadequate relief. There was no provision for Saturday or holidays, and the children came back at the end of their holidays in a dazed, tired, and listless condition. Now the State proposed that henceforth, when local authorities undertook the work of feeding, the Exchequer would contribute one-half of the expenditure. Then there were further grants for health work among children in other directions. The Government were already finding the money for the medical inspection and treatment of children. Then they proposed there should be a grant for physical training, for open-air schools—he was told that about one-fifth or one-sixth of the children stood in urgent need of training of that kind—for dealing with tuberculosis in children, and there was an epidemic grant to help the education authorities to close the schools without loss in the case of an epidemic in the neighbourhood. There were special grants for schools for deformed children, for the feeble-minded and crippled, and it was also proposed to aid the schools for mothers—the maternity centres, which had sprung up in many parts of the country, and were doing admirable work.

More Financial Support for National Insurance.

In regard to the National Insurance Act, Mr. LLOYD GEORGE said: I come to National Insurance. Experience of the work of the National Insurance Act shows the direction in which financial support is needed. I made several statements on the point earlier in the session. It shows that in spite of the abnormal work of the first year the resources provided fully justified the actuarial estimate. I further stated that under no conditions would any subsidies be given to make up deficiencies due to mismanagement and malingering; but that there were cases where well-managed societies attracted an unusual proportion of bad lives, or were limited to classes subject to special sickness and disability, and above all the working of the Act revealed an appalling amount of sickness amongst married women, especially under certain conditions, a fact which was quite unknown before the Act came into operation. I promised that if deficiencies in these cases were due not to malingering and not to mismanagement, but to circumstances of a kind over which no society had any control and which demand the assistance of the Government and the support of the State, it would be the business of the Government to recommend to the House of Commons some means of dealing with them. That is what we propose to do. I do not think it would be desirable at this stage to go into the details. The whole of the burden will not fall upon the State. The societies also must come to the rescue. I do not think it would be desirable for me to give the general character of the proposals. I think it would be desirable, before they are finally settled that there should be further consultations with the societies. It is perfectly clear that the Government will have to make a substantial grant in aid of these very abnormal and, as far as some of them are concerned, distressing cases. We have to deal with the deposit contributors. We anticipated that there would be 900,000 deposit contributors, but as a matter of fact there are only 400,000. The rest have all joined societies, and out of the 400,000 there are very few who have not joined societies because they cannot join them. There are some who, out of choice, prefer to remain outside. There are others who probably believe that in a few years they will be out of insurance because they will be above the insurance line, and who therefore do not think it worth while to join societies. The number of those who become deposit contributors because they have no other option is small, and it is a dwindling number; but those are people who deserve a little encouragement and support from the State. We propose to do something for them, something for certain cases of arrears of unemployment. We propose also to establish a system of medical referees who will not merely be a check upon malingering but will be expert medical men, who can be called in for an opinion where there is a serious case of illness and the ordinary medical man on the panel is not quite sure and wants to get a second opinion. It is proposed to establish clinics in convenient centres to assist the panel doctors to coöperate in difficult cases. We propose to assist the organisation of a system of health lectures, such as exists in Germany, which has done a vast amount of good in spreading a knowledge of the principles of health among the insured population. The total of that for insurance will be £1,250,000 for the whole of the United Kingdom.

HOUSE OF LORDS.

THURSDAY, APRIL 30TH.

Midwives (Scotland) Bill.

The House went into Committee on the Midwives (Scotland) Bill.

Lord BALFOUR of BURLEIGH, who is in charge of the Bill, said that there were a large number of amendments to the Bill on the notice paper. They were all, however, of a drafting nature. He promised that he would move the recommittal of the Bill after the amendments were agreed to.

The amendments were inserted in the Bill without discussion.

The Bill was afterwards ordered to be recommitted.

HOUSE OF COMMONS.

THURSDAY, APRIL 30TH.

Superintendent of Statistics, General Register Office, Ireland.

Mr. KELLY asked the Chief Secretary to the Lord Lieutenant of Ireland whether the superintendent of statistics in the General Register Office was about to retire; and, if so, in view of the fact that this was a small office with a total staff of only about 30 established officers, would he revert to the practice of promoting one of these officers to the vacant superintendentship.—Mr. T. W. RUSSELL (on behalf of Mr. BIRRELL) replied: The Registrar-General informs me that the answer to the first part of the question is in the negative. The latter part does not therefore arise.

Mr. W. ABRAHAM asked the right honourable gentleman whether the position of superintendent of statistics in the General Register Office, Dublin, had always been filled by a permanent civil servant on vacancies occurring since the establishment of the office; whether there was at present any special reason why another general medical practitioner should be deemed to have special qualifications for discharging clerical or administrative duties in this office; whether the work of classifying causes of death and of segregating the various diseases which could be accepted as causes of death had been very fully and efficiently dealt with by the present superintendent of statistics; in the event of further questions of this nature arising, would they be referred to Sir William Thompson, M.D., the Registrar-General; and would he resist any recommendation to appoint anyone who was not an established civil servant to the vacancy.—Mr. T. W. RUSSELL replied: This is practically the same question as the last, and the same answer applies.

Cases of Anthrax.

Mr. JOWETT asked the Home Secretary whether he was aware that on Wednesday, April 15th, a washbowl minder employed by Messrs. Campbell and Harrison, a branch of Woolcombers, Limited, of Bradford, contracted anthrax in the course of his employment and died of the said disease on the following Saturday, and that on the same day a washbowl feeder in the employment of Messrs. John Cure and Co., another branch of Woolcombers, Limited, contracted anthrax in the course of his employment, and he also died of the same disease; and whether he would say how many cases of anthrax had occurred among the employees of each of the two firms mentioned, respectively, during the period of years 1900 to 1913 inclusive, distinguishing between fatal and non-fatal cases.—Mr. MCKENNA answered: I have seen reports of the two cases mentioned, in both of which the disease was apparently contracted previously to and developed during the Easter holidays. The total figures for the two firms referred to for the period 1900 to 1913 are: For the former firm 18 fatal and 36 non-fatal cases; for the latter 6 fatal and 14 non-fatal cases. As my honourable friend is aware, an inquiry is now being conducted by a Departmental Committee into the dangers from anthrax in the Bradford woollen industries and the working of the existing regulations.

Coroners in England and Wales.

Mr. MCKENNA informed Mr. HIGHAM that there were in all 366 coroners in England and Wales, of whom 82 were paid by fees.

Food Inspection at the Port of London.

Answering Mr. HUNT, Mr. HERBERT SAMUEL (President of the Local Government Board) stated that including the medical officer of health and his assistants there were 19 officers engaged in the work of food inspection in the Port of London Sanitary District. During the year 1913 8,718,365 cwt. of meat (excluding poultry and game) were imported into London. The inspection of imported meat devolved upon officers of the Port Sanitary Authority, working in conjunction with the officers of customs. He had received no complaint as to the inadequacy in number of the inspectors. The responsibility for the inspection did not lie with the Local Government Board, but with the local authority.

The Use of the Geneva Cross.

Mr. LANE-FOX asked the Under Secretary of State for War why men of the National Reserve who had served in the Royal Army Medical Corps regulars or auxiliaries were not permitted to wear the Geneva Cross of the Royal Army Medical Corps on parade, provided they were properly registered under the new classification and were restricted to wearing it on parade; and would he consider the granting of this privilege to these men.—Mr. TENNANT wrote in reply: Under Article 23 of the Geneva Convention the emblem of the red cross on a white ground and the words "Red Cross" or "Geneva Cross" cannot be used except to protect or indicate the medical units and establishments and *personnel* and *matériel* protected by the Convention.

MONDAY, MAY 4TH.

A Resolution of the Royal College of Surgeons in Ireland.

Mr. NEWMAN asked the honourable Member for St. George's-in-the-East, as representing the Insurance Commissioners, whether he had received a resolution passed by the Royal College of Surgeons in Ireland on April 19th expressing regret that insured persons who make their own arrangements for medical benefit might obtain treatment from non-qualified persons, and deploring that recognition should be given and provision made for the payment of public money to persons who had no legal qualification to practise and concerning whose medical knowledge there existed no sort of guarantee; and, if so, whether he proposed to take any action in the matter.—Mr. WEDGWOOD BENN replied: My right honourable friend's attention has already been drawn to the resolution in question, which appears to be based on a misapprehension as to the scope of the Regulation alluded to. I would refer the honourable Member to the reply which I gave on March 6th.

Panel Practitioners and Lapsed Insured Persons.

Mr. DENNISS asked the honourable Member for St. George's-in-the-East what steps were taken in England, Wales, and Scotland, respectively, to secure that names of insured persons who had died, or ceased to be insured, or had removed from an area in which they were formerly insured, were taken off the list of the panel doctor whom they had selected or to whom they had been assigned, and whether the arrangements made for this purpose were working satisfactorily; whether there was any reason to believe that some doctors had been paid on account of insured persons in respect of whom they were not entitled to be paid: and what instructions, if any, had been given to Insurance Committees to prevent the possibility of a panel doctor being paid in respect of an insured person for whom he was not entitled to make a claim.—Mr. WEDGWOOD BENN answered: Arrangements were originally made for the notification by Approved Societies to Insurance Committees of the deaths and lapses from insurance and removal of their members. As regards removals, a new system has been instituted which enables their notification by societies to be dispensed with. As regards deaths and lapses, the procedure is being revised in connexion with the new system and as a result of the experience gained. Cases may have occurred in which, notwithstanding the advice of the Commissioners, advances had been made to practitioners out of proportion to the amount due to them, but any such overpayments would of course be adjusted on the final settlement.

Balance of Medical Fund.

Mr. DENNISS asked the honourable Member for St. George's-in-the-East when the Commissioners expected to be in a position to inform Insurance Committees in England, Scotland, and Wales, respectively, of the amount of the medical fund at their disposal, in order that they might be in a position to make a settlement with their doctors and chemists for the year ending on Jan. 12th last.—Mr. WEDGWOOD BENN said in reply: The necessary accounting operations are now in progress and will shortly be completed.

Domiciliary Treatment for Tuberculosis.

Mr. ASTOR asked the honourable Member for St. George's-in-the-East whether Insurance Committees had power to provide, and did in fact, when required, provide, to persons in receipt of domiciliary treatment for tuberculosis, the following among other articles of food, viz., milk, butter, eggs, bread, fish, and meat, and if this had been done in England, Scotland, Ireland, and Wales.—Mr. WEDGWOOD BENN wrote in reply: All Insurance Committees are empowered to provide, and do in fact provide, for persons in receipt of sanatorium benefit in the form of domiciliary treatment such accessories as form part of the treatment, and are prescribed as such on medical grounds, and milk, butter, eggs, fish, and meat have in particular instances been thus given; but Insurance Committees are not empowered to provide maintenance by way of general relief.

TUESDAY, MAY 5TH.

Uncertified Deaths.

Mr. HIGHAM asked the President of the Local Government Board whether his attention had been drawn to the fact that the Regulations in regard to uncertified deaths recently issued by the Registrar-General, with the approval of the Board, had not been issued in the manner provided for in Sections 44 and 48 of the Registration Act, 1874, and whether he proposed to withdraw the Regulations.—Mr. HERBERT SAMUEL replied: I am aware of the provisions contained in the enactments referred to. The requirements of Section 44 of the Act of 1874 refer to orders made in pursuance of that section. These were not such orders. The answer to the last part of the question is in the negative.

Atkinson.—On April 29th, at Elton Cottage, Newnham-on-Severn, Glos., the wife of Jackson Atkinson, M.B., B.S.Lond., of a daughter.

Cleminson.—On May 3rd, at Albert-road, Gloucester Gate, Regent's Park, the wife of Frederick John Cleminson, M.C., F.R.C.S., of a son.

Godson.—At The Craig, Laxey, Isle of Man, the wife of John Edward Godson, M.D., of a daughter.

Pinching.—On April 26th, at Frampton-on-Severn, Stonehouse, Gloucestershire, the wife of W. G. Pinching, M.R.C.S., L.R.C.P., of a daughter.

Strong.—On April 25th, at Magor House, Mon., the wife of Gravenor Robert Strong, M.B., B.S. Lond., of a daughter.

Whitaker.—On May 3rd, at Evershot, Dorset, the wife of Alfred Gurth Whitaker, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

Hosford—Walker.—On April 30th, at St. Pancras Church, London, by the Rev. L. E. Metcalfe, vicar, Alfred Stroud Hosford, M.R.C.S. Eng., L.R.C.P. Lond., youngest son of the late Dr. John Stroud Hosford and Mrs. Hosford, of The Grove, Stratford, E., to Beth, daughter of the late Robert Walker, Esq., of The Banks, Horsley, Wylam-on-Tyne.

Parkin—Fenwick.—On April 29th, at Matfen Parish Church, by the Rev. C. C. Petch, Alfred Parkin, M.D., M.R.C.P., F.R.C.S., son of the late George Parkin and Mrs. Parkin, of Gateshead, to Elizabeth, daughter of the late Matthew Fenwick, of Steelridge, and Mrs. Fenwick, of South Clarewood, Corbridge. At Home—56, Jesmond-road, Newcastle-on-Tyne, June 10th and 11th.

Thomas—Codrington.—On April 28th, at Holy Trinity Church, Exmouth, Robert Stanley Thomas, M.D. Cantab., to Violet Francis, youngest daughter of Colonel and Mrs. Codrington, Chippenham House, Exmouth.

Ward—Newman.—On April 25th, at St. Margaret's, Westminster, by the Rev. Geoffrey Gordon, chaplin to the Westminster Hospital, Gordon Reginald, second son of the late John Barron Ward, of Streatham, S.W., and Mrs. Ward, of 2, Perham-crescent, West Kensington, to Gladys Mary, daughter of the late Frederick Newman, of Barnsley, Yorks, and Mrs. Newman.

DEATHS.

Abercrombie.—On April 30th, at Augill Castle, Brough, Westmorland, John Abercrombie, M.D. Cantab.

How.—On April 30th, suddenly, of cerebral hæmorrhage, Frederick Field Lawrence, L.M.S.S.A.

Keith.—On May 1st, at St. Ives, Swanage, William Gregory Keith, M.B., C.M. Edin., L.R.C.S., L.R.C.P. Edin., late Colonial Surgeon Ceylon Medical Service, aged 68.

Pinder.—On May 1st, Thomas Henry Pinder, Surgeon, of Edenwood, Wilmslow, and Temple Chambers, Brazennose-street, Manchester, *in his 71st year.*

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MOSQUITO EXTERMINATION IN KINGSTON: JAMAICA AND THE YELLOW FEVER PROBLEM.

IN the joint session of the Sections of Tropical Medicine and Hygiene and of Naval and Military Medicine at the International Medical Congress in 1913, Dr. J. J. Van Loghem, whose experience as director of the Institute of Tropical Hygiene in Amsterdam lends weight to his words, referred to the very real danger of the transference of yellow fever to Asia and Australia on the opening of the Panama Canal. In our issue of Jan. 31st a leading article dealt with the protection of India from yellow fever. Undoubtedly the West Indies and the East Indian Islands, as being the nearest possible inflammable centres, are equally or more interested. Dr. Van Loghem, in his remarks already cited in THE LANCET of August 23rd, 1913 (p. 570), referred to his own personal experience as to the frequency of stegomyia in the Dutch East Indian Archipelago and on board ships trading between Dutch East Indian ports. The services rendered by sanitary science in stamping out yellow fever and malignant malaria in the Canal Zone were fully considered about a year ago (March 29th, 1913) in a leading article in THE LANCET. The subject is, in short, engaging medical attention everywhere. In a recent report by Dr. Angus G. Macdonald, the medical officer of health of Kingston, Jamaica, the systematic steps there taken for the extinction of the stegomyia and the education of the people in specific sanitary measures are detailed. Measures are administrative and educative. The administrative consist of house-to-house visitations, which engage the part-time work of seven sanitary inspectors, special mosquito investigation, to which one sanitary inspector devotes his whole time, the removal of all water-holding receptacles on dumping grounds, and so forth. When larvæ are found at the house-to-house search leaflets are distributed detailing the measures to be taken for exterminating them, and these measures are, moreover, carefully explained. A second visit is paid in such cases in three weeks and a third three weeks later. If on either revisit larvæ are still found, the chief sanitary inspector or the medical officer himself pays a visit and repeated instruction is persisted in. But little opposition is met with. As to educative measures, the entire staff of the Health Department are "trained to be apostles of hygiene," so that an attempt is made to reach the small things of life in the homes of the people, and the interest of the schools and the churches is also enlisted in the work of special education. Larvæ have been found in order of frequency in barrels and jars, tubs and pans, flower vases and pots, cast bottles and tins, bark pans with floor-staining liquid, a chicken pan, shells, cocoanuts, calabashes, gourds, and so forth. They have not been found in tree holes or under dripping taps. Gutters, "faulty down-outs," sanitary arrangements generally, and the numerous receptacles about wharves are kept under supervision always, irrespective of incrimination as mosquito harbourers. Dr. Macdonald, from recent observation of the Panama Canal Zone, is not afraid to say that the stegomyia limitation in Kingston compares favourably with that in Colon or Panama. Certainly the results of recent work, as indicated in the tables submitted with the report, could hardly be bettered. In Kingston in 1912, with an estimated population of 57,800, were paid 22,906 visits, with 1389 finds of larvæ, a ratio of 6 per cent.; in 1913, with an estimated population of 58,312, 24,352 visits were made, with only 378 finds of larvæ, or only 1·55 per cent. Confirmatory evidence of the most practical kind appears in the malaria returns of the Public Hospital, yellow fever being entirely absent. The admissions were 723 in 1910, 349 in 1911, 95 (of which 32 came from outside Kingston) in 1912, and 113 (57 from outside) in 1913. The decline in the malaria mortality is even more marked; it fell from 126 in 1910 to 72 in 1911, and to 17 in 1912 and 1913. These figures establish a very satisfactory record for Kingston, and suggest that this erstwhile hotbed of "Yellow Jack" will be well able to take care of itself.

CARAVANNING.

THE caravan season is here again. Mr. Harris Stone, the secretary of the Caravan Club, has a brief article on the Coming Growth of Caravanning in *The Selborne Magazine* for May, in which he points out the great advantages of caravan life for people with a fixed but very limited income. A small fixed income at the present day means fixture, localisation, stagnation; no hope of change, no looking forward to brighter prospects. Caravanning offers freedom, movement, variety, open-air life, a riddance of the unnecessary impedimenta with which we incontinently encumber ourselves, an adjustment of the environment to oneself instead of *vice versâ*. It is all this to the energetic, hardworking, methodical, and educated mind, and far superior for such than a small home or a flat; but it possesses no attraction for the loafer, the thriftless, the grumbler, and the incapable. There are people who have lived in their caravans, owning no other home, for years, and many who now spend the summer thus.

"MILLIBARS."

To the Editor of THE LANCET.

SIR,—Can any of your readers tell me how the "unit" on the new scale for measuring "atmospheric" pressure has been arrived at? In the Weather Reports this morning *the Times* gives the following equivalents:—

1024·1 millibars = 30·24 inches.
1016·4 ,, = 30·02 ,,

From these figures I find that 1000 millibars = 29·53 inches, or 750 millimetres. Since 760 millimetres (or 29·92 inches) is the standard barometric pressure, one would have imagined that 1000 millibars = 760 millimetres would have been more accurate.

I am, Sir, yours faithfully,
New Southgate, N., May 4th, 1914. BETA.

THE KINEMA AND THE CHILD'S HEALTH.

Dr. G. W. M. Joseph, medical officer of health of Warrington, in his annual report states that kinematograph exhibitions may have a potent effect in spreading infectious and contagious diseases. The health of children may also be affected unfavourably by the action of the moving pictures on the eyes, by sanitary defects, and by late hours. It would appear that defective children who are being treated at the clinic are being excluded from school, but they may go to picture shows. Dr. Joseph is of opinion that no children of school-age should be admitted to evening kinema performances.

AN UNUSUAL CASE OF SELF-MUTILATION.

To the Editor of THE LANCET.

SIR,—In relation to Lieutenant-Colonel C. Milne's remark in THE LANCET of April 18th that "it is inconceivable that the English proverb, 'To cut off one's nose to spite one's face,' ever had a literal application," I have to record a case now in this asylum of a man aged 35 who 10 years ago not only cut off his nose but his testicles as well.

I am, Sir, yours faithfully,
H. WILLIAM DUDGEON, M.D. Durh.
Khanka Lunatic Asylum, Egypt.

⁂ In this connexion, we recall the extraordinary case of the man who tore his tongue out by the root, reported in THE LANCET of Feb. 5th, 1898, p. 384.—ED. L.

EARLY MEDICAL MOTOR-CARS.

To the Editor of THE LANCET.

SIR,—I remember reading in THE LANCET of March 20th, 1897, that a physician in Youngstown, Ohio, Dr. Carlos Booth, was the first medical man in the United States to make use of a motor carriage for the purpose of working his practice. Further back still I recall in THE LANCET of Jan. 4th, 1896, a long article, with an illustration of a quaint-looking motor-car, suggesting that medical men might be beginning to take an interest in these vehicles for the purposes of their practices. Fourteen years later, in an article in your issue of Jan. 1st, 1910, on the Medical Profession and the Early History of the Motor-car, it was stated that although the first electric carriages for ordinary roads were used in 1889 by Mr. Magnus Volk, of Brighton, the first petrol car was introduced into England from France in 1895. It might be interesting to put on record who was the first British medical man to use a motor car in his practice.

I am, Sir, yours faithfully,
London, May 4th, 1914. HISTORICUS.

"PAN YAN" PICKLE.

Messrs. Maconochie Bros., Ltd., of Millwall, London, E., have forwarded to us a specimen of this pickle, which they state is a [illegible] of the finest fruits, com[illegible] [illegible] important [illegible] the [illegible] has been [illegible] The Pan Yan pickle [illegible] a very [illegible]

SALVARSAN SUPPOSITORIES.

W. H.—A small portion is absorbed which is often sufficient to produce a beneficial effect upon systemic lesions, without irritating the rectal mucous membrane. But suppositories of salvarsan can hardly be expected to cure the disease, and we know of no case in which they should be used in preference to an injection.

◆

B. R. K. (Lahore).—The address of the New York Association for Improving the Condition of the Poor is 105 E. Twenty-second Street, New York City, U.S.A. The secretary may be able to supply the full report on the home treatment of pulmonary tuberculosis to which our correspondent refers.

Miss G. B. Jacobi.—In our paragraph on Medical Practice in Sweden last week the words "first class" were meant to be taken literally, as might have been gathered from what went before.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Dr. A. D. Waller: The Various Inclinations of the Electrical Axis of the Human Heart.—Part 1A. The Normal Heart. Effects of Respiration.—Dr. D. H. Thursday.—5 P.M., Major A. J. Hull, R.A.M.C.: The Transport of Wounded in War.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY, Board Room of the Great Northern Central Hospital, Holloway-road, N.

Thursday.—9 P.M., Presidential Address:—Dr. T. W. Parry: Prehistoric Man and his Early Efforts to Combat Disease.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

Monday.—4 P.M., Dr. H. Davis: *Clinique (Skin).* 5.15 P.M., Lecture:—Dr. R. F. Fox: Effects of Heat and Cold.

Tuesday.—4 P.M., Dr. J. Taylor: *Clinique (Medical).* 5.15 P.M., Lecture:—Dr. R. F. Fox: Methods of Hydrotherapy.

Wednesday.—4 P.M., Mr. R. Howard: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. R. F. Fox: Medicinal Springs and Baths.

Thursday.—4 P.M., Dr. H. Campbell: Clinique (Medical). 5.15 P.M., Lecture:—Dr. R. F. Fox: Indications of Hydrological Treatment.

Friday.—4 P.M., Dr. J. Donelan: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday.—10 A.M., Dr. Simson: *Diseases of Women.* 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, *Dr. Bernstein: Pathological Demonstration.* 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. *Pritchard: Bacterial Therapy Department.* Mr. B. Harman: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Diseases of the Rectum.

Tuesday.—10 A.M., Dr. Robinson: Gynæcological Operations. Dr. Owen: *Demonstration of Cases in Wards.* 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Mr. Baldwin: Diseases of the Rectum.

Wednesday.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women and Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Diseases of the Rectum.

Thursday.—9 A.M., Dr Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Mr. B. Harman: *Diseases of the Eye.* 5 P.M., Lecture:—Mr. Baldwin: Diseases of the Rectum.

Friday.—10 A.M., *Dr. Robinson*: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., *Lecture:—Dr. Bernstein: Applied Pathology.* 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases *of the Throat, Nose, and Ear.* Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Mr. Baldwin: Diseases of the Rectum.

Saturday.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the *Throat, Nose, and Ear.* Mr. B. Harman: Diseases of the Eye. 12 noon, Lecture:—Mr. Souttar: Surgical *Anatomy of the Abdomen.* 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

Monday.—Out-patient Demonstrations:—10 A.M. Dr. H. B. Carlill: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Dr. G. Holmes: Demonstration of Neurological Cases.

Tuesday.—Out-patient Demonstrations:—10 A.M., Dr. C. E. Zundel: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.15 P.M., Sir Malcolm Morris: Skin. 4.30 P.M., Special *Lecture:—Dr. T. Lister: The Artificial Pneumothorax.*

Wednesday.—Out-patient Demonstrations: 10 A.M., Dr. H. B. Carlill: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery. 4.30 P.M., *Special Lecture:—Dr. J. Taylor: Some* Clinical and Pathological Aspects of Nervous Disease.

Thursday.—*Out-patient Demonstrations*:—10 A.M., Dr. H. R. Prentice: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Sir StClair Thomson: Tuberculosis of the Air-passages.

Friday.—Out-patient Demonstrations:—10 A.M., Dr. C. E. Zundel: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin. ——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford: Medicine. 3.15 P.M., Mr. L. McGavin: Surgery. 3.15 P.M., Lecture:—Mr. L. McGavin: Gall stones and the *Surgery of the Bile Ducts.*

Saturday.—Out-patient Demonstrations: 10 A.M., Dr. H. R. Prentice: *Medical.* Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——10 A.M., Col. Barry: Radiography.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Gynæcological (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

Tuesday.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Nose, Throat, and Ear (Mr. H. D. Gillies). X Ray and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. Whiting).

Wednesday.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye *(Mr. Dorell).*

Thursday.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical *Out-patient (Dr. A. J. Whiting)*; Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

Friday.—2.30 P.M., *Operations. Clinics:—Medical Out-patient* (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. P. *Brooks).* 3 P.M., *Medical In-patient (Dr. G. P. Chappell.*

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL (University of London), Albert Embankment, S.E.

Lectures in Advanced Medical Subjects:—

Tuesday.—5 P.M., Dr. H. Maclean: Carbohydrate Metabolism in Health and in Diabetes.

GUY'S HOSPITAL MEDICAL SCHOOL, London Bridge, S.E.

Course of Lectures on Industrial Medicine:—

Friday.—Lecture II.:—*Dr. F. Shufflebotham*: The Post-mortem Appearances Associated with Lead Poisoning.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, Medical School, City-road, E.C.

Monday.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Cardiac Department, Dr. Stott; Out-patient Department, Dr. Phear, Dr. S. Thompson. 3 P.M., Wards, Dr. Phear.

Tuesday.—9 A.M., Laryngological Department, Mr. Mant. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. M. Leslie, Dr. B. King; Operations, Mr. A. Evans. 3 P.M., Wards, Dr. White. 4 P.M., Wards, Dr. M. Leslie

Wednesday.—2 P.M., Wards, Dr. A. Davies; Out-patient Department, Dr. Drysdale, Dr. Kellie. 4 P.M., Wards, Dr. Drysdale. 4.30 P.M., Roentgen Ray Department, Dr. Jordan.

Thursday.—9.30 A.M., Dental Department, Mr. G. Thomson. 10 A.M., Cardiac Department, Dr. Stott. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient *Department, Dr. Phear, Dr. S. Thompson.* 4.30 P.M. Laryngological Department, Mr. Mant.

Friday.—1.30 P.M., *Department for the Prevention of Consumption.* 2 P.M., Wards, Dr. Calvert; Out-patient Department, Dr. M. *Leslie, Dr. B. King.* 5 P.M., Lecture-Demonstration:—Dr. Calvert: The Treatment of Pulmonary Tuberculosis by Artificial *Pneumothorax.*

Saturday.—10 A.M., Out-patient Department, Dr. Drysdale, Dr. *Kellie.* 11.30 A.M., *Roentgen Ray Department*, Dr. Jordan.

LONDON HOSPITAL MEDICAL COLLEGE (University of London), Clinical Theatre, London Hospital, Mile End-road, E.

Monday.—Lecture on Tuberculosis.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.

Course of Demonstrations for Post-Graduates:—

Friday.—4 P.M., Dr. E. H. Colbeck: Demonstration of Heart Cases.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

Tuesday.—3.30 P.M., Clinical Lectures:—Dr. *R. Russell: Syphilitic* Affection of the Nervous System.

Friday.—3.30 P.M., Clinical Lecture:—Dr. G. Stewart: *Compression* Paraplegia.

THE THROAT HOSPITAL, Golden-square, W.

Monday.—5.15 P.M., Special Demonstration of Selected Cases.

Thursday.—5.15 P.M., Clinical Lecture.

LONDON LOCK HOSPITAL, 91, Dean-street, Soho, W.

Special Course of Instruction in Venereal Diseases, for Post-Graduates and Students, with Practical Demonstrations of the Various *Methods of Treatment*:—

Monday.—Clinics:—1 P.M., Mr. Ryall; 6 P.M., Mr. Gibbs.

Tuesday.—Clinics:—2 P.M., Mr. *Lane*; 6 P.M., Mr. Paterson.

Wednesday.—Clinic:—6 P.M., Mr. Shillitoe.

Saturday.—Clinic:—2 P.M., Mr. *McDonagh.*

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

Tuesday.—Manchester and Salford *Hospital for Skin Diseases*, Quay-street.—4.30 P.M., Dr. G. H. Lancashire: Some Common Parasitic Skin Diseases.

Wednesday.—*Royal* Infirmary—4.30 P.M., Dr. Melland: Some More Minor Ailments.

Thursday.—Ancoats Hospital—4.30 P.M., Dr. W. J. S. Bythell: Ionisation and Electrolysis.

UNIVERSITY OF SHEFFIELD, at the *Royal* Hospital, West-street, Sheffield.

Post-Graduate Course on Syphilis:—

Tuesday.—3 P.M., Dr. Hallam and Dr. Skinner: Clinical Diagnosis. Demonstration of Type Cases. *Clinical Methods of Detecting* Spirochætes in Lesions.

Friday.—3 P.M., Dr. Hallam and *Dr. Skinner*: Principles of Treatment. Local and General. Mercury, Methods of Administration, Dosage, &c. Iodides. Salvarsan and Neosalvarsan, Method of Preparation, Dosage, Modes of Administration, (*a*) intramuscular, (*b*) intravenous. Complications. *Contra-indications.* Demonstration of Technique.

UNIVERSITY OF LEEDS, Great Hall of the University, College-road.

Special Lectures on Medical Subjects:—

Wednesday.—4 P.M., Mr. T. S. P. Strangeways: Rheumatoid Arthritis and Allied *Conditions.*

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Version. 11 A.M., Examination of Patients and Minor Operations.
TUESDAY.—10 A.M., Major Operations.
WEDNESDAY.—10 A.M., Obstetrical Lecture: Extraction in Breech Cases. 11 A.M., Examination of Patients and Minor Operations.
THURSDAY.—10 A.M., Major Operations.
FRIDAY.—10 A.M., Gynæcological Lecture: The Nature and Diagnosis of Ovarian Tumours. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

May 31st–June 5th (London, South Kensington).—Sixth International Congress of Social Work and Service.
Sept. 8th (Begins) (Manchester).—Meeting of the British Association.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Arris and Gale Lecture

ON

THE DEVELOPMENT OF THE HEART IN MAN IN RELATION TO ITS FUNCTIONAL ACTIVITY.

Delivered before the Royal College of Surgeons of England on March 2nd, 1914,

BY DAVID WATERSTON, M.A., M.D. EDIN.,
F.R.C.S. EDIN.,
PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LONDON.

MR. PRESIDENT AND GENTLEMEN,—I wish to bring under your notice some results of the observations on human embryology which have been made in my laboratory during the past year or two. The subject I have selected deals with problems of embryology which have a distinct relationship to adult anatomy and physiology, as well as to clinical work, and the observations will therefore prove of interest to those who are engaged in clinical study and practice as well as to those who are mainly occupied in laboratory work.

THE PROBLEMS OF HUMAN EMBRYOLOGY IN RELATION TO THE HEART.

As an anatomist I feel that no explanation is necessary for discussing problems of human embryology, for we have come to recognise the fact that knowledge of the adult human body is incomplete without a comprehension of the successive stages through which all the parts and organs of the body pass before the adult condition is attained. From another standpoint, we now regard the adult (type of) organism which forms the usual object of study in anatomical laboratories, as representing only one of the phases of human structure, and the sphere of embryology includes not only the changes which occur during the intra-uterine life of the embryo, but also the numerous and great changes which occur after birth.

We have expanded that narrow view of embryology which looks to it merely for an explanation of teratological defects, and in place of that, we look to embryology to elucidate and to explain many of the problems of infantile, adolescent, and senile structure, with which are connected the physiological peculiarities which characterise these divisions of human life.

This aspect of embryology is nowhere better illustrated than in the problems which arise in connexion with the structure and function of the heart. The general lines of the development of that organ have been worked out in considerable detail, but the recent advances which have been made in our knowledge of the anatomy and physiology of the fully developed heart have drawn attention to some features of its development which have not yet been fully elucidated, and it seems to me that a knowledge of its development is likely to throw some additional light upon its functional activity in the adult.

During the whole process of its development the heart is a functioning organ—in other words, from the time of its first appearance it is actively engaged in carrying on the circulation in the body of the embryo and in the placenta. In this respect it differs from the other organs of the body. During the process of their development, with a few exceptions, they are not physiologically active, or their activity during fœtal life is of a different kind from their adult function. Since this is so, it seems likely that an investigation of the functional activity and the regulating mechanism of the heart during fœtal life would reveal facts of some importance in connexion with the study of the adult heart.

THE SINU-ATRIAL NODE AND THE ATRIO-VENTRICULAR NODE AND BUNDLE.

The special advances which have occurred within recent years include the knowledge that has been gained of the atrio-ventricular bundle, and also of the sinu-auricular node of Keith and Flack.

The first of these structures, as you are aware, forms a connecting band between the musculature of atria and the ventricles of the heart. It can usually be detected by macroscopic examination, and it originates in a node of tissue situated in the wall of the right atrium, near the orifice of the coronary sinus. From that node the bundle passes towards the ventricular septum, below the membranous portion of the septum, and divides into right and left branches—the right branch passing downwards in the septal wall of the right ventricle and the left passing through the ventricular septum to the wall of the left ventricle. Each division of the bundle breaks up into branches, which ramify under the endocardium of the ventricular chambers. The network which the branches form is a very complex one, and it can best be demonstrated by a method of injection, for the bundle and its branches are surrounded by a loose connective tissue, or possibly even a large space, into which Indian ink can be injected, and the fluid passes along the course of the branches.

The sinu-auricular node of Keith and Flack is a node of tissue with distinctive histological characters, placed near the entrance of the vena cava superior, on the lateral wall of the right atrium, at the junction of the sinus venosus and atrium in the sulcus terminalis. There may be other connexions between atrium and ventricle, but I do not propose to discuss the evidence for the existence of these.

Of the function of these structures the atrio-ventricular bundle appears to regulate the sequence of the atrio-ventricular contractions, while the sinu-atrial node has been termed the "pace-maker of the heart," and in it there originates the wave of contraction which spreads over the whole atrium.

THE EMBRYOS STUDIED.

The material which I have prepared and studied consists of some specimens from a series of human embryos. Sections of the first and youngest of these were entrusted to me by Mr. Henry Wade and by Professor B. P. Watson, while for some of the others used in this investigation I am indebted to my friend, Dr. H. J. F. Simson, and to these gentlemen I wish to record my grateful thanks.

The work of examining these embryos and of making the models has been carried out in my laboratory in King's College, and I wish to acknowledge the untiring assistance I have received from my skilled laboratory assistant, Mr. Weston.

HEART OF EMBRYO 3 MM. IN LENGTH.

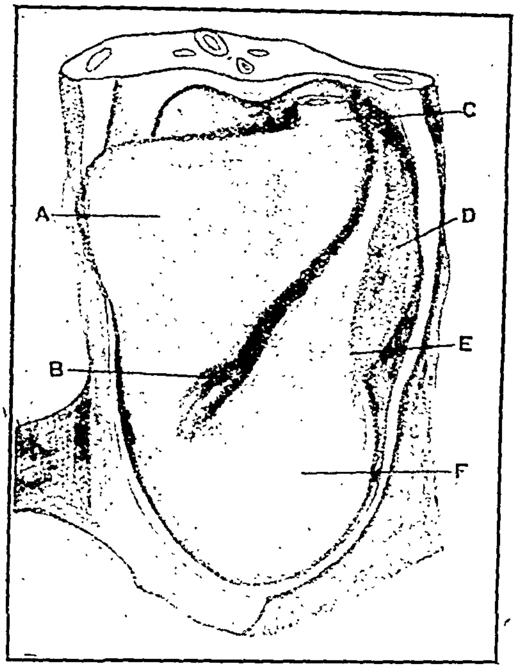
I begin at the stage at which the embryonic heart presents itself as a twisted tube-like structure, dilated and contracted at intervals, enclosed in the pericardial sac.

The first specimen shows the heart from a human embryo almost 3 mm. long, and presumably in about the third week of development. The external form of the embryo, with its yolk sac, amnion, chorion, were reconstructed at a magnification of 50 diameters. The model of the heart and adjacent part of the trunk has been reconstructed in wax plates at a magnification of 200 diameters.

Features of the Heart.

Viewed from the front the ventricle and the bulbus cordis are seen. (Fig. 1.) The former is a conical chamber which already forms the apex of the heart, while the bulbus cordis forms a long irregularly tubular structure which lies to the right of the ventricle and then above it. It communicates with the ventricle by a slightly constricted orifice, and passes onwards to bend up into the conus arteriosus.

FIG. 1.



Reconstruction of heart of human embryo three to four weeks old. A, Bulbus cordis. B, Bulbo-ventricular groove. C, Conus arteriosus. D, Auricle (atrium). E, Auricular, or atrial, canal. F, Ventricle.

The bulbus cordis is a chamber of the heart whose wall is formed by myocardium, and which in animals such as the dogfish carries semilunar valves internally. In the embryo it is lined by a tissue from which valves are afterwards formed. The ventricle and bulbus are separated by a long oblique groove—the bulbo-ventricular groove.

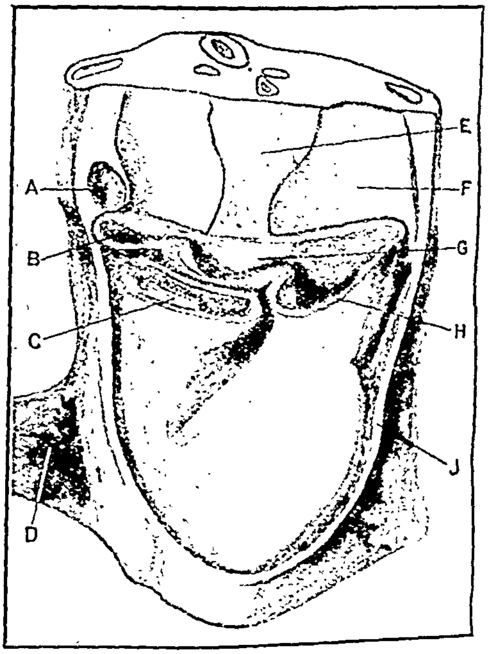
The atrial, or auricular, portion of the heart lies dorsally and in a cranial direction, and only small portions are seen from the front. The dorsal view of the heart shows the large single atrium and the sinus venosus opening into its right portion, after receiving the great veins. Even at this stage a pulmonary vein is present which opens into the atrium to the left of the sinus venosus. The atrial canal lies entirely on the left side.

Internal Structure.

At this stage of its development the heart wall consists of two distinct layers—an endocardial tube, invested externally by myo-epicardial wall. These two layers of the wall are in some parts widely separated, the endocardial tube forming a very narrow tube in the interior of the space included by the myo-epicardial wall. (Fig. 2.) The space between the two tubes is filled by an extremely delicate reticulum derived from the endothelial tube. In the atrial canal and in the bulbus the greatest interval is found between the two walls. In the sinus venosus, atrium, and lower portion of the ventricle the lumina of the two tubes correspond, and the myo-epicardial wall is lined by the flattened endocardium. Fig. 2 shows the relative size of the two tubes in the bulbus cordis region. Horizontal section of the model shows the relative position and size of the chambers. (Fig. 3.)

The myo-epicardial wall forms a continuous sheet, and extends without interruption from the sinus venosus to the bulbus cordis. The cells forming it already show some fibrillation, indicating their transition into contractile muscle cells. The veins entering the sinus venosus have no definite muscular walls; they are merely endothelial-lined spaces containing blood. The myo-epicardial wall is thickened in the ventricle and in the lower part of the bulbus, and already trabeculæ are present in those regions. The endothelial tube also forms a continuous wall, the lumen of which is dilated at intervals.

FIG. 2.



Internal structure of Fig. 1. A, Right duct of Cuvier (cut). B, Sinus venosus. C, Endothelial tube of bulbus. D, Amnion. E, Dorsal mesentery of heart. F, Dorsal wall of body cavity. G, Auricle (atrium). H, Myo-epicardial wall of auricle. J, Pericardium (divided).

Valvular apparatus.—The sinu-atrial junction is guarded by a valve, consisting of a single flap, formed by an infolding on the right side of the sinu-atrial junction—the right venous valve. (Fig. 3.) There is no valvular apparatus either at the atrio-ventricular junction, nor in the ventricle and bulbus, unless the loose connective tissue which separates the endothelial tube and the myo-epicardial wall in these two regions has some such action.

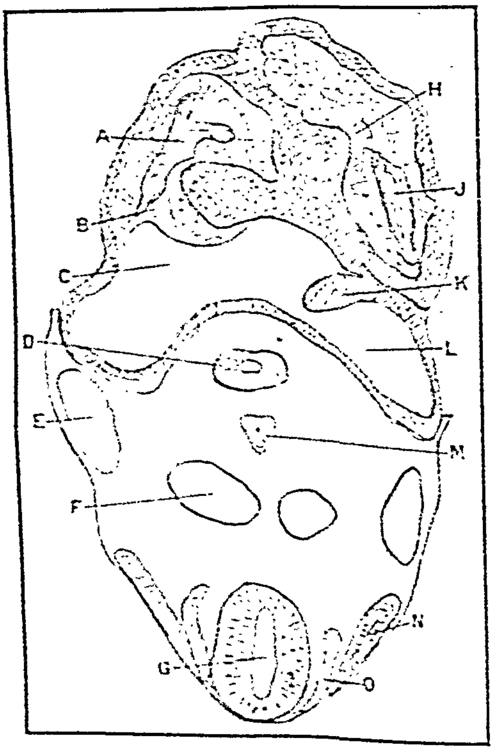
The atrial wall is infolded slightly on its anterior and cranial aspect, apparently from the pressure of the conus arteriosus, and this infolding is the earliest indication of the vertical septum which later on divides the atrium into two halves.

Mechanism.

There is no evidence of the formation of any specialised tissues in the wall, and the mechanism of the heart at this stage consists in a rhythmic peristaltic contraction which begins at one end of the muscular tube, in the sinus venosus, and passes thence along the wall to the arterial end.

If we seek in the animal kingdom for a comparison with a heart at this stage we find it in the dogfish, whose heart consists of exactly similar chambers, occupying very much the same relative position, and resembling very closely in all details the corresponding parts in the young human embryo. The nature of the circulation which can be carried on by a heart of this kind is of the simplest character—namely, one in which there is a single circulation, of what may be called the "venous type," through the heart, for the heart in the fish has merely to drive the blood to the gill arches, where it is oxygenated and whence it passes to the rest of the body.

FIG. 3.



Transverse section of three to four weeks embryo. A, Endothelial tube in muscular (atrial) canal. B, Dorsal connective tissue reticulum. C, Cavity of auricle (atrium). D, Lung bud. E, Left duct of Cuvier. F, Left dorsal aorta. G, Spinal cord. H, Connective tissue reticulum of bulbus. J, Endothelial tube of bulbus. K, Right venous valve. L, Sinus venosus. M, Oesophagus. N, Somite. O, Neural crest.

It may be stated with assurance that at this stage of development there is no question of the existence of nerve control. There is no sympathetic system, and the cranial and spinal nerves have not developed beyond the most primitive stage, in which the neural tube has a neural crest on each side, but has no ventral roots growing out from it.

HEART OF EMBRYO 6 MM. IN LENGTH.

From the stage at which the heart is a continuous tube I now pass to the next stage of its development, in which a subdivision of the primary chambers is occurring.

The model shows you the heart of an embryo 6 mm. in length, or approximately six weeks old. The external form of the embryo shows that at this stage the limbs are beginning to appear. The model of the heart has been reconstructed at a magnification of 100 diameters. (Figs. 4, 5, and 6.)

The anterior view shows a large bulbo-ventricular chamber, divided partly into right and left halves by an indentation on its lower margin. From the right half of this chamber the distal portion of the bulbus cordis ascends vertically and passes into the conus arteriosus. The atrium (or auricle) has expanded, and its right and left wings appear on either side of the ascending stem.

Arrangement of Chambers.

The arrangement of the chambers is as follows. (Fig. 8.) The sinus venosus, now relatively reduced in size, opens into the right posterior wall of the atrium by a pouting slit-like orifice with right and left margins. It is very like the ileo-cæcal junction, and from the upper border of the orifice a fold passes vertically in the atrial wall, like the retinacula of the ileo-cæcal value. The atrium is incompletely divided into right and left halves by a vertical septum—septum primum—which is perforated at its upper dorsal portion to form the secondary foramen ovale. The atrium is of large size, and throughout the heart there is an extraordinary difference between the size of the chambers and the size of the communications which connect them.

The atrio-ventricular canal is short, and is now divided into a right and a left aperture by the fusion of its upper and lower boundaries in the centre, leaving on each side a small orifice, the right and left atrio-ventricular orifices. (Figs. 7 and 8.) This division has been effected by the development of two large endocardial cushions, of which I shall say more subsequently.

The ventriculo-bulbar chamber is incompletely divided by a septum growing up from below, and from its right upper angle the bulbus cordis ascends. The proximal portion of the bulbus is lined by two large endocardial cushions which pass for some distance down into the ventriculo-bulbar cavity (Fig. 8), while in the distal portion there are four such swellings placed around the circumference of the tube. It must be noted that the muscular wall of the whole organ is still continuous throughout, but changes are occurring in it.

In the division of the atrium and the imperfect division of the ventriculo-bulbar chamber, the condition of the heart resembles that of the amphibian, in which there is a morphological division of the auricle, and a functional subdivision of the ventricle and bulbus, in response to the need for carrying on both a venous (pulmonary) circulation and an arterial, left-sided, systemic circulation.

Minute Structure.

The chief interest in the structure of this specimen, from the standpoint of its functional activity, lies in the regions of the sinus venosus and the atrial canal.

1. *Sinus venosus.*—The sinus venosus opens into

the atrium by a narrow slit-like orifice, whose characters have already been described. The structure of the sinus wall shows a distinct modification in the appearance of the sinu-atrial node. In the upper part of its right wall a well-marked thickening is found, and the histological features of this thickening show that it is not of the same structure as the other portions of the wall. Furthermore, at the sinu-atrial junction a distinct vessel is found lying in the wall, and around it is the modified tissue. It may be pointed out that the position of the sinu-atrial node can be identified in the fully developed heart most readily by the existence of a distinct vessel which traverses it. There can be little doubt that the appearances found in the present specimen indicate the earliest formation of the sinu-atrial node as a modification of the tissue forming the wall of the sinus. (Fig. 7.)

On the left wall of the sinus opening an endocardial cushion is found, and the tissue of the sinu-atrial node appears to pass in the dorsal wall of the sinus towards this cushion. The tissue composing the node consists of rounded cells with large, round, deeply staining nuclei. The adjacent cells of the muscle wall of the atrium and sinus on the other hand, are spindle-shaped, and the cell substance is fibrillar and their nuclei are elongated.

2. *Atrial canal.*—The atrial canal is much modified by formation of endocardial cushions. In the earlier specimen this canal was lined by the delicate connective tissue reticulum all round. In place of that former lining, two large masses of connective tissue are present, situated one anteriorly or above and the other posteriorly, and two smaller cushions are making their appearance, one on the lateral side of each of the *a.-v.* openings. (Fig. 7.) The larger cushions are not confined to the region of the canal, but the anterior passes to the lower border of the septum primum, while the posterior one passes in the floor of the atrium towards the sinu-atrial orifice.

Above the atrial canal two pulmonary veins are found passing to the left atrium. Where they approach the atrial wall the muscular coat of that chamber is continued on to these veins, but a considerable part of the atrial wall is at this level composed of connective tissue, and not of muscle. The superior, right and left walls of the atrial canal are intact—that is, they consist of a sheet of definitely muscular tissue, which passes from the atrial wall to the wall of the ventricle. The inferior (posterior) wall is also complete, but its internal surface, in contact with the posterior endocardial cushion, is very irregular. An inner and outer layer can be recognised; between them is a loose connective tissue. (Fig. 9.)

This formation apparently precedes the appearance of tissue which can be definitely recognised as "bundle" tissue, and it occurs in the position in which the node and proximal part of the bundle are laid down. In embryos slightly more advanced than this specimen a bundle of fibres, staining somewhat deeply, is found occupying this position. It can be identified from the surrounding tissue by its staining properties. Whether it is an ingrowth into the reticular tissue described here or is derived by transformation of the reticular tissue I am unable to say. From the evidence presented of the local formation of the sinu-atrial node I am inclined to think that the atrio-ventricular node and bundle are also formed locally.

The external layers of the posterior wall of the atrial canal can be traced onwards to the upper portion of the muscular interventricular septum.

Mechanism.

It is interesting to note what the mechanism of the heart at this stage is.

The muscular coat is continuous, and no doubt the contraction is largely rhythmical in character. The node in the sinus wall constitutes a starting point for the contraction, which from that point sweeps onwards over the muscular wall of the atrium, atrial canal, and ventricle. But now a pulmonary circulation is definitely established, pulmonary veins open into the left division of the atrium, and it is essential that the contraction of the mouths of these veins should occur as the earliest stage of atrial contraction to prevent blood being driven back along them. The necessity for this probably affords the explanation of the extension of the sinu-atrial nodal tissue to the left side, towards the pulmonary veins.

The condition of the heart is that of the amphibian, and in the amphibian it has been shown that a sinu-atrial node such as I have described exists.

The musculature of the atrial canal is still intact, and the two *a.-v.* orifices open into a common chamber, from which the blood is expelled by a single orifice into the distal half of the bulbus cordis.

SUBSEQUENT STEPS IN DEVELOPMENT.

The subsequent steps by which this single channel is divided into two can be briefly explained by short reference to the figures. The endocardial cushions lining the bulbus cordis meet and fuse in their upper parts, and so constitute an aorto-pulmonic septum, dividing the cavity in a spiral fashion into the stem of the pulmonary artery and the aorta. From this septum an extension occurs downwards and obliquely to the right. The septum meets the right end of the anterior endocardial cushion and encircles the right *a.-v.* orifice, while more anteriorly it passes down to meet the upgrowing interventricular septum and blends with it. Thus the flow of blood from the left *a.-v.* orifice passes on one side of the septum into the aortic channel, while the blood entering by the right *a.-v.* orifice passes on the other side of the septum to the pulmonary artery. From this it will be seen that the membranous part of the septum, the vestibule of the aorta, and the entrance to the pulmonary artery are all formed from the downgrowth from the bulbus septum.

It is not my purpose here, however, to describe in detail the changes which are associated with the formation of the valves of the heart beyond saying that the *a.-v.* valves are formed from the endocardial cushions which surround the *a.-v.* openings and which project into the ventricles, while the semilunar valves of the aorta and pulmonary artery are formed from endocardial cushions in the distal part of the bulbus cordis.

HEART OF EMBRYO 20 MM. IN LENGTH.

I now pass to the next stage of the development of the heart, in which the bulbus cordis, in its distal part, has become completely divided into pulmonary artery and aorta, and the right and left ventricle are separated from one another by the completion of the interventricular septum from above by a downgrowth from the septum of the bulb. At this stage the lungs are more fully developed, and the specimens I show are from an

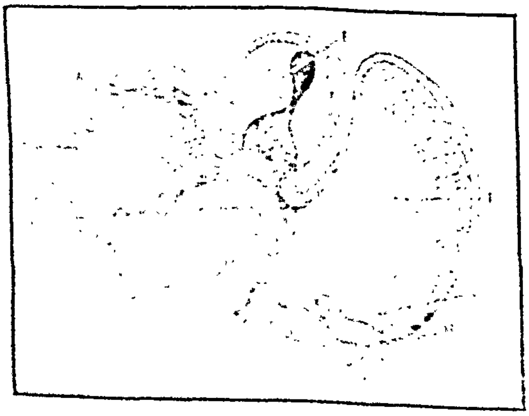
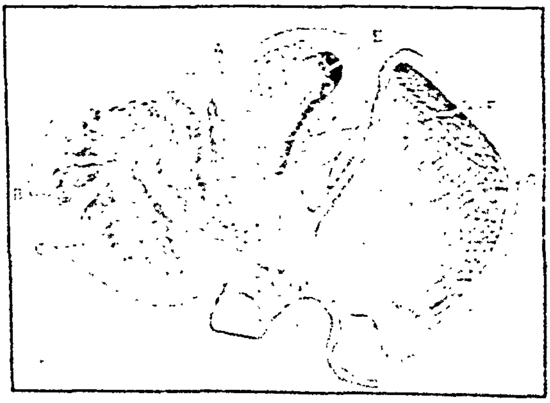
FIG. 8.



[illegible]

FIG. 9.



[illegible]

embryo of 20 mm. length, or about the eighth week of development.

Structure.

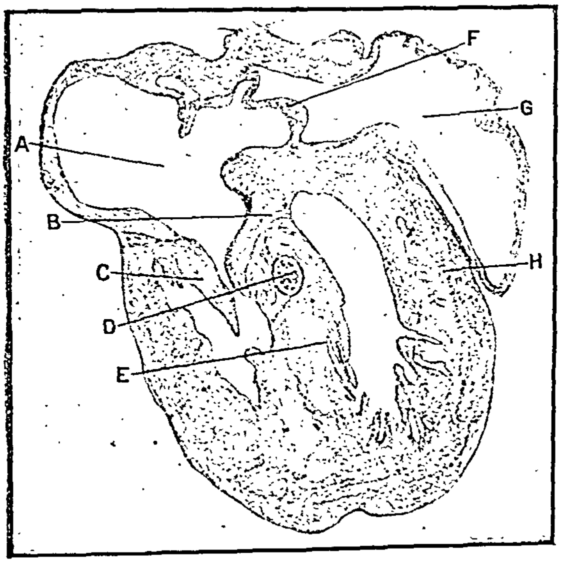
The heart is now practically a four-chambered organ, though the right and left atria are still connected by the opening of the foramen ovale secundum, and in its shape it resembles more closely the adult heart.

The sinus venosus has been largely incorporated into the right atrium, and the pulmonary veins are fully developed.

Atrial canal.—The atrial canal can still be recognised as the narrow band which surrounds the junction of atrium and ventricle. The epicardial layer overlying the original muscular wall of this portion has become very much thickened and has invaded the underlying muscular tissue and largely replaced it. The endocardial cushions surround the atrio-ventricular orifices, and their margins projecting into the ventricular chambers have become undermined to form the cusps of the tricuspid and mitral valves.

The aorto-pulmonic septum has grown down, and fused with the right margin of the anterior endocardial cushion and also with the upper margin of the interventricular septum. At the junction of the two parts, the reticular tissue noticed in the former specimen, and derived from the posterior wall of the atrial canal, has now developed further and encloses the *a.-v.* bundle. The bundle itself forms a compact, darkly staining mass, surrounded by a loose layer of areolar tissue, and it can be traced in a downward direction to the right and left surfaces of the ventricular septum, while in the opposite direction it passes towards the anterior portion of the auricular septum, and in this way the original connexion of the atrium and ventricle is maintained. (Figs. 10 and 11.)

FIG. 10.



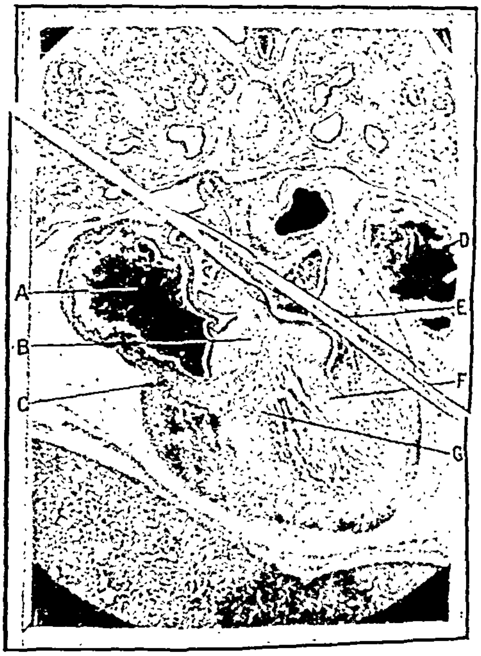
Horizontal section of heart of 20 mm. human embryo (seven to eight weeks). A, Right auricle (atrium). B, Auriculo-ventricular junction. C, Marginal cusp of right *a.-v.* orifice. D, Auriculo-ventricular bundle, in ventricular septum. E, Interventricular septum (muscular portion). F, Inter-auricular septum, septum primum. G, Left auricle (atrium). H, Muscular wall of left ventricle.

Mechanism.

The mechanism at this stage is now practically that of the adult heart. The interior of the right atrium is subdivided by partial septa, so that the current of blood from the vena cava superior is directed to the atrio-ventricular foramen, while that from the vena cava inferior is directed more to the foramen ovale.

The muscular contraction of the atria, originated in the sinu-atrial node can now sweep over the atrial chambers, and the impulse can be conveyed from the atrial wall to the walls of the two ventricles. The two ventricles can now beat simultaneously and not as they did in the original peristaltic movement, when the wave of contraction affected the left ventricle and then passed from it to the more distal portion of the ventriculo-bulbar chamber which gives rise to the right ventricle.

FIG. 11.



Horizontal section at a lower level than Fig. 10 (photograph). A, Right auricle (atrium). B, Auriculo-ventricular bundle. C, Auriculo-ventricular junction, muscle wall being broken down by connective tissue. D, Left auricle (atrium). E, Left *a.-v.* orifice. F, Muscular interventricular septum. G, Trabeculæ in right ventricle.

At this stage, too, the nerve connexions of the heart have been fully formed, and so the characters of the cardiac contractions can be brought into harmony with the special needs of other parts of the body.

The evidence does not show that the atrio-ventricular bundle is derived from nerve tissue, but rather that the connexions it possesses with the central nervous system are established after the bundle has formed, and that the nerves are of secondary importance in regulating the cardiac rhythm. They have rather the function of coördinating the movement of the heart as a whole with the demands of the circulation throughout different parts of the body.

CONCLUSIONS.

The conclusions may be summarised as follows:—

1. In the first stage of its development the heart is a self-regulating organ. Its rhythmic activity is shown by peristaltic waves of contraction which sweep over it from end to end, and at this stage it

possesses a continuous muscular coat. It is quite independent of the central nervous system.

2. In the next stage—i.e., when the primitive chambers are being divided—a new mechanism arises in the form of a node of specialised tissue situated at the junction of sinus venosus and atrium, which passes thence to the dorsal wall of the atrium and the region of the pulmonary veins. This is the first of the nodal tissues to appear, and is the precursor of the sinu-atrial node of the adult heart.

3. The *a.-v.* bundle and node make their appearance about the time of the further division of the chambers of the heart, as a bundle of fibres lying under the posterior endocardial cushion of the atrial canal, and extending from the atrial wall to the ventricular muscular septum. The evidence goes to show that this bundle is derived from the tissues in which it appears, and that from the first it is surrounded by a sheath of loose connective tissue. Fibres and cells from the central nervous system invade this bundle, and also go to other portions of the heart wall, but the intrinsic regulating mechanism appears to arise independently of the nervous system, and is connected only secondarily through that system with other parts of the body.

THE DIAGNOSIS OF APPENDICITIS.

BY WILLIAM H. BATTLE, F.R.C.S. ENG.,
SENIOR SURGEON TO ST. THOMAS'S HOSPITAL, ETC.

THERE is too much tendency when considering the diagnosis of this disease to forget that it varies extremely in its manifestations, and that it must be regarded from various standpoints according to its mode of onset and the stage to which it has advanced when first seen by the skilled observer. It is not advisable to labour the subject; indeed, from the number of communications which appear on appendicitis it is almost necessary to apologise for anything likely to add to the literature of that disease, and in order to avoid any unnecessary elaboration I will put forward briefly a few points which may be useful. It will be best to make a classification into (1) acute appendicitis; (2) appendicitis which has ended in localised suppuration; (3) appendicitis with spreading inflammation of the peritoneum; (4) cases in which there is appendicitis with suppuration, but in which the defensive barriers have been broken down and the pus suddenly and generally diffused; and (5) recurrent attacks. It is the first of these to which I intend to limit my remarks.

Acute Appendicitis.

In acute appendicitis, limiting the term to acute inflammation of the appendix seen within the first 48 hours, there will be a variation in the symptoms in different individuals according to age, sex, position of appendix (pelvic, iliac, retrocæcal, outer side of cæcum), nature of the lesion in the appendix, and whether the attack is a first one or not. The amount of pain varies; it may be severe though transient, referred to the iliac fossa, unaccompanied by appreciable fever or more than a temporary increase in the pulse-rate. There may be but little tenderness, and that of short duration, yet at the removal of the appendix (if this is done early) the surface may be coated with lymph. At other times the patient may call out with pain, having been awakened from sleep, and becomes quite collapsed, so that the administration of stimulants is necessary to bring him round. This pain may continue for hours and then stop suddenly or pass off gradually. It differs widely, then, in intensity. Most agree that it is bad. Usually it is referred to the region of the umbilicus and passes later to the right iliac fossa, where it becomes localised. When the appendix is in the pelvis the pain is less clearly defined, but is said to be "low down"; it is often increased by pressure on the right lower rectus, which is rigid. Vomiting is usually present, coming on soon after the onset of the pain. It does not always continue for long, but if it does so the attack is probably of a severe nature. In many attacks of appendicitis there is no vomiting, but there is almost always a feeling of nausea. There may be no shock or collapse, but in some instances this may be very marked.

To these symptoms there are added those of fever—a quickened pulse and respiration and a rise of temperature, mostly to 101–3°F., but it may be much higher (106°). The patient looks ill, has a furred tongue and foul breath, whilst the bowels are usually confined; in severe cases diarrhœa is common. Even in the more acute cases the tongue may be quite clean. Examination of the abdomen shows diminished respiratory movements, chiefly in the hypogastric region. It feels stiff and may be rigid, especially about the lower part of the right rectus, which is doing its duty of guarding the inflamed appendix from disturbance. Tenderness may be widely spread, but is most easily elicited on pressure over the right iliac fossa, or if the appendix is in the pelvis on rectal or vaginal examination. Frequency of micturition and dysuria are present when the inflamed appendix is in the pelvis.

It is very seldom that we can find any tumour in the iliac fossa within 24 hours of the onset of an acute attack; the rectus muscle prevents even a distended appendix of considerable size from being felt; there is often a sense of fulness underneath the muscle, especially if the appendix is retrocæcal. An enlarged appendix may, however, be felt when the patient is under an anæsthetic. A large number of these acute attacks luckily undergo resolution, the pain subsides, the temperature falls, the pulse-rate diminishes, and convalescence begins at the end of two or three days. As the rigidity of the rectus muscle diminishes, a swelling is felt about the appendix which indicates a localisation of the inflammatory process, and the illness is, for the time, practically over. In a few days more this swelling has quite disappeared. Unless the medical man draws the attention of the patient to this swelling it is probably not noticed by him, and when questions are asked in a later attack as to a former swelling—a valuable point in the history—the patient does not know. And in most cases there is no history of rectal or vaginal examination sent with the case. Although the pulse and temperature may be normal the patient is not safe until the swelling has quite gone.

With the cessation of pain there may be a loss of the protective contraction of the muscles, although there is still tenderness in the region of the appendix. This sometimes occurs within 48 hours of the commencement, and may be wrongly regarded as a sign that the attack has subsided, being only of a mild character, yet on operation a gangrenous appendix may be found. The explanation may be that the appendix is shut in behind the cæcum or encircled by the omentum, for when it has given way into the general peritoneum there is usually no relaxation of the muscles, and the pulse increases in frequency.

What I wish to emphasise is that attacks of acute appendicitis vary very much, and ideas of the gravity of a particular attack will vary somewhat according to experience. Regard any attack of abdominal pain with suspicion if with it there are fever, rigidity of muscles, and tenderness in the lower abdomen, especially if that tenderness is over Clado's point.

There may be quite another picture presented within the first 48 hours—that of a more severe storm which seems likely to hurry the patient into his grave before he can be relieved. The commencement may be a rigor, the temperature very high, the effect on the nervous system and on the heart profound, whilst the local signs of peritonitis quickly increase in severity and extent from hour to hour. In these cases there is no hesitation as regards operation; the patient's friends demand it, he is so very ill. The other cases also cry for early operation, but the cry is often unheeded because the receiver is not trained to messages pitched in the lower key. We should be all agreed of the need for operation in all cases as soon as possible. It is in the interest of the patient that it should be done. If we could cut short an attack of typhoid fever by removing the appendix we should do it at once in every case, and be very glad to do it. A neglected attack of appendicitis may be more deadly than one of typhoid and far more distressing. Last year there was a good deal of discussion in the medical world as to the need for immediate operation—at all events within the first 48 hours: there were few dissentient voices amongst the surgeons who expressed opinions. Most had settled this question long before, but the general agreement expressed may have helped some who were uncertain to make up their minds finally in favour of early operation. Another question which arose from this was whether a surgeon could give an opinion of any value as to the nature of the pathological change in the appendix on which the attack depended. I have contended that he can do so in a large number of instances, not always, because it is often quite impossible to get the real history of the case, or the signs and symptoms are obscure. In this respect the surgeon is much better placed than the physician, for the former sees the case and examines the appendix when removed, whilst the latter rarely sees the appendix, and very often is not told of the pathological changes which were found at the operation. I did not see Mr. Edmund Owen's letter[1] in which he denied the accuracy of this statement until long after it had appeared in THE LANCET, therefore there did not seem any urgency for a reply when I did so. The essential thing, need for early operation, had been granted, the other which was of far less importance could wait. When I wrote my original letter I had in my mind three consecutive cases of operation in private in which the state of the appendix had been stated correctly, and after reading Mr. Owen's letter I took the next series during an emergency week at St. Thomas's Hospital. Operation was successful in all. The cases which were seen in private were as follows.

CASE 1 (seen with Dr. A. Charpentier and Dr. F. E. Walker).—A boy, aged 6, who complained of a sudden abdominal pain in the early morning of the previous day. He was seen at 5.30 P.M., and during the day had suffered from severe abdominal pain and vomiting. His pulse had been rapid all the day and was still the same—120. The temperature had been high—102-103° F. The boy was breathing rapidly and his alæ nasi were working. He was quite intelligent and had a clean tongue; still, there was a look of distress about him. His abdomen was rigid, not moving with respiration, and there was some dulness in the right flank. A diagnosis of commencing peritonitis due to gangrenous appendix, which contained a concretion, was made. Operation was carried out as soon as possible. Appendix 4 inches. There was a gangrenous patch limited to the part surrounding a concretion. Thick very offensive purulent fluid about the cæcum and in the pelvis. All the forceps applied to the shortened meso-appendix came away before a ligature could be applied, but there was no bleeding, both arteries and veins being thrombosed. Drainage.

CASE 2 (seen with Dr. G. F. Cooper.)—A married lady, aged 28, who admitted that she had suffered from occasional attacks of abdominal pain, during which she had vomited at times, but denied that she had ever had appendicitis, was seen at 5 P.M. She had been awakened with abdominal pain on the previous morning and this continued all day, but was not very bad until night, when there was a sudden increase in it with vomiting and a rapid pulse. She was given morphia and was still showing the effects of it, but was better in some ways, the temperature being 100° F. and the pulse 100. There was some tenderness of the abdomen, but not much rigidity; there was also resistance with a more generalised tenderness spreading to the left. The tongue was dry, the bowels confined, and there was slight general distension of the abdomen. Appendix 4½ inches, irregularly enlarged and acutely inflamed. There was a constriction about 1¼ inches from the proximal end with dilatation beyond, which had not ruptured. It was full of offensive purulent fluid. There was also a concretion, which was pressed to the narrowed part of the canal, and the mucous membrane over it was gangrenous, but had not yet yielded. There was some free fluid in the pelvis. As the appendix was removed intact it was not considered necessary to drain the wound.

CASE 3 (with Dr. Frank Deas and Dr. James Scott).—A married lady, aged 35, giving a history of two previous attacks of appendicitis five months and three weeks previously respectively. After "a party" on the previous night she had felt some uneasiness in the abdomen, and at 10 o'clock next morning had severe pain in the abdomen which lasted for some hours and then ceased rather abruptly. She vomited twice. When examined there was no pain, but the surface of the abdomen was bright red from the application of fomentations. There was tenderness in the iliac fossa with some muscular rigidity, but she could draw a full breath without pain and was not distended. The pulse was 140. This was not regarded as a serious sign because she was neurotic and very much afraid of operation, having lost a favourite brother after an operation for appendicitis. A diagnosis was made of perforation of the appendix beyond a stricture, the stricture being towards the distal extremity. This opinion enabled us to postpone operation until after removal to the Cottage Hospital, a matter of great importance as the house was new, not yet fully furnished, and badly lighted from an operator's point of view. Appendicectomy was performed at 10 o'clock next morning. Appendix 5 inches long; strictured about an inch from the tip; dilated beyond and perforated at the tip, which was adherent to a coil of bowel. There was very little free fluid.

Three patients were operated on in succession during a night in October, 1913, and the following are brief accounts of their cases.

CASE 4.—The patient was 8½ years old. The illness had begun two days before with a dull pain in the right side. The pain grew worse next day, and before admission was very bad and localised to the right iliac fossa. The bowels acted after castor oil. The patient had vomited once the night before admission. The temperature was 101° F. and the pulse-rate 120. The lower abdomen did not move well. There was marked rigidity below the umbilicus and the greatest tenderness in the iliac fossa. There was dulness in both flanks. The patient was lying on his back with the knees flexed, and was evidently in great pain. An incision was made through the right rectus. There was offensive fluid in the peritoneum, but to no great amount. Appendix 4 inches, large, retrocæcal, adherent, and much inflamed generally. Two concretions were present, and over these gangrenous patches which had given into the general peritoneal cavity. Drainage through the wound brought foul-smelling fluid away for some days. Ten days after operation the pulse was still over 100.

---

[1] THE LANCET, June 21st, 1913, p. 1762.

CASE 5.—The patient was 14 years of age. There was no history of previous illness. Two days previously, in the morning, he had felt pain, localised at first in the right iliac fossa, but spreading later across the lower abdomen. He continued work till the morning of admission, when he was obliged to remain at home because of the severity of the pain. He was flushed and looking very ill. The abdomen moved very little. There was general rigidity of the muscles, most marked on the right side. Tenderness was general, chiefly over McBurney's point. On examination per rectum the patient complained of being tender on the right side, but nothing abnormal could be felt. No change in percussion note. The temperature was 93° F. and the pulse 80. The appendix was large and acutely inflamed, lying to the outer side of the cæcum, resembling in size and shape an adult human thumb. A concretion was present in the terminal part over which the mucous membrane was becoming gangrenous. No drainage, although there was some thin fluid in the pelvis.

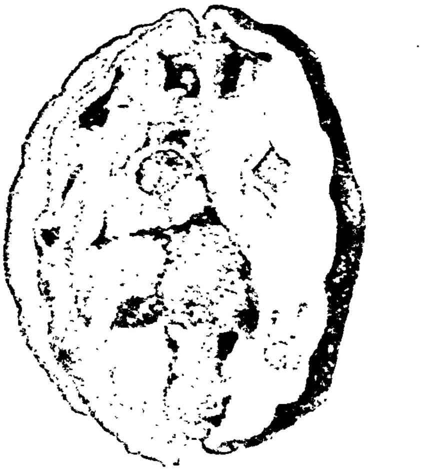
CASE 6.—The patient, aged 16, gave a history of one previous attack of pain in the right iliac fossa for which he had been treated medically elsewhere. Twelve hours before admission he had complained of pain in the right iliac fossa, but had not been sick. The abdominal wall was not rigid or tender anywhere excepting over McBurney's point, where there was slight tenderness. There was no distension and no local swelling. The pulse was 110. The appendix was 3 inches long and twisted. The meso-appendix was bound down by adhesions of old standing, giving the appendix the appearance of being partly strangled. There was lymph on the surface, and an acute inflammation of the distal end with thickening. No drainage.

In Case 6 the diagnosis was not quite correctly given. It was thought that a strictured appendix was the cause of the symptoms, but as a matter of fact the appendix was twisted, and this twist produced an obstruction to the lumen, the effect being that of a stricture. Another case may be given in confirmation of the fact that it cannot always be said what is the correct state of the appendix, notwithstanding the certainty that there is inflammation of it.

CASE 7.—A man aged 21 came into hospital during the same week as the subjects of the last three cases with a history of an attack of sudden pain at 2 o'clock in the morning. By 6 o'clock the pain was so violent that he decided to come up to the hospital, and he vomited several times on the way. He had never had any similar attack, and his bowels had acted the day before without medicine. The abdomen moved well on respiration, but he still complained of severe pain in the right iliac fossa. There was some tenderness over the appendix, with rigidity of the lower rectus. There was no distension, a pulse of 72, and a temperature of 93·4° F. Operation later in the day showed a thickened appendix attached to the lower part of the cæcum by inflammatory exudation. It was about 3 inches long. Inside was a patch of ulceration with a sloughing centre and thickened base, on which there were two bristles of small size, and a metallic concretion.

On the other hand, there are various acute diseases which render the diagnosis from acute appendicitis difficult and almost impossible, and from time to time some case is met with which adds to the list. Renal calculus has frequently given symptoms which have led to a wrong diagnosis when in the right kidney, and when it has passed into the ureter, but a case of transference of symptoms from the left kidney to the right side of the abdomen is practically unknown; therefore the following case is important.

CASE 8. [illegible]—The patient, aged 23, was admitted on June 19th, 1912. She was suffering from an acute abdominal illness, and gave the following history. About four years previously she had a similar attack with pain in the abdomen, and was ill for 15 weeks. Two years ago she had a repetition of the symptoms, and suffered off and on for a year. She was under the care of a medical man who advised her to have the appendix removed. Five days ago she became ill again with pain in the right lower abdomen and vomiting. The pain continued, and two days later she again vomited. Dr. Godfrey saw her on the 10th, and found her complaining of pain in the same part of the body, with resistance to pressure and tenderness. The temperature was 102° F., and the pulse rapid. On the 12th there was still a temperature varying from 100° to 102°. She looked ill, had a furred tongue with offensive breath and pulse 100. The abdomen did not move well, and she complained of pain which was limited to the right lower part, where there were tenderness and rigidity of muscle. Nothing abnormal was found on examination beyond this, and rectal examination was negative. The bowels were constipated. In a day or two the symptoms subsided, but returned with severity, so she was sent to St. Thomas's Hospital on June 19th. The abdomen was then very tender all over, but not rigid. Nothing abnormal could be found. Temperature, 100·6°; pulse, 120; tongue still furred and breath foul; specific gravity of urine 1012, acid, heavy deposit of urates, no albumin. The appendix was removed; it was normal. Examination of the right side of the abdomen revealed nothing abnormal; the ovaries and tubes were healthy, and the uterus was retroverted. She vomited a good deal, almost continuously for two days, but the temperature came down to normal. On the 25th it was reported that the Widal test for typhoid was negative. On the 26th she was examined very thoroughly by the resident physician, who found no evidence of disease of the chest. The vomiting, which continued, appeared to be functional, whilst the temperature, which was still irregularly high, might have been due to a sore throat of which she was complaining. On this day she was removed to a small ward and placed in charge of special nurses. July 5th: The patient had ceased to vomit. General condition improving. Had been complaining of pain in her right loin for some time. The urine was acid, with a slight trace of albumin, but with no blood; some pus cells were found. She continued to complain of pain in the right loin, so was sent to the X ray department to have the right kidney examined. The report was returned: "There are six shadows in the left kidney region. The right kidney is normal." This was on July 17th, and on the 22nd she was again X rayed. The same group of shadows were seen. She was still complaining of pain in the right side. There was also a change in the character of the urine, the specific gravity of which was 1015, pus being present with [illegible] in large quantities, as also [illegible] casts. On July [illegible] the left kidney was removed. Examination [illegible] that it was full of stones and there was very little [illegible] left. Its appearance is well shown in the illustration. It measured about [illegible] in length. The surface was somewhat



Calculi of left kidney which produced symptoms resembling those of acute appendicitis.

irregular but smooth, and the capsule non-adherent. The largest stone was lying in the pelvis and practically filled it. The smaller stones were scattered throughout the substance of the organ. At the upper end there was a small cystic space containing a rounded stone. After the operation the patient improved quickly, but even on August 3rd she still complained of occasional pain in the right side. She left on August 15th. From Oct. 28th to Nov. 12th she complained of pain accompanied with fever (temperature 101° to 102°) and sickness. The pain was along the course of the left ureter, where she had tenderness also. The ureter was examined in the X ray department, but nothing abnormal could be seen.

In the interesting address on Reflex Pains in Diseases of the Abdominal Viscera, by Mr. A. E. Maylard,[2] he refers to the occasional transference of pain in renal calculus to the opposite kidney. In this case there was not only a transference of the pain but a condition of fever, probably due to a temporary blocking of the renal pelvis, which for a time prevented the escape of pus into the urine. The combination of pain in the right side of the abdomen, tenderness over the iliac fossa, with rigidity of the muscles and fever, made the resemblance to an attack of acute appendicitis very close. The absence of any swelling in the abdomen, owing to the fact that the kidney was so small, or change in the urine during the attack rendered diagnosis impossible when first seen. At that period in the illness, had it been appendicitis, there should have been evidence of swelling either in the iliac fossa or in the pelvis on rectal examination; in the absence of this we did not feel justified in recommending an operation. Exploration was obviously required on a return of the symptoms.

Harley-street, W.

COMMON ERRORS IN THE TREATMENT AND DIAGNOSIS OF DIETETIC DISORDERS IN INFANTS.[1]

BY ERIC PRITCHARD, M.A., M.D. OXON.,
M.R.C.P. LOND.,
PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN; PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, ETC.

ON thinking over the mistakes which I have made in the diagnosis and treatment of cases of illness in infants attributable in any way to dietetic causes, I am surprised to discover that a preponderance of these arose in connexion with disturbances of the motor functions of the alimentary tract rather than with disturbances of the digestive functions proper.

When an infant suffers from so-called indigestion we are very apt to think of undigested food and inactive or absent ferments, and we turn lightly to the evidence of chemical analysis and of naked-eye examination of vomitus or stools to supply the key to the situation. I do not wish in any way to belittle the value of the information thus afforded; but the point I would particularly emphasise is that a very large number of cases of so-called indigestion prove intractable to treatment because we fail to recognise that the symptoms are due to a perverted or incoördinated performance of the motor functions—a result dependent more on *habit* than on the particular qualities of the food which for the time being the infant may be consuming.

The neuro-muscular mechanisms which control the locomotion of food through the body are extremely complicated, and they are largely dependent for their efficient working, not only during infancy but during the whole of life, on the nature of their early experiences and education. Each link in the complicated chain of neuro-muscular coördinations which effects the locomotion of food through the alimentary tract, whether it be associated with the act of deglutition, with the rhythmical openings and closings of sphincters, or with the peristaltic contractions of muscles, is dependent on a delicate and complicated reflex, which is initiated in its due chronological order by the act which immediately precedes it, and thus for the harmonious working of the whole series one indispensable condition is the harmonious coöperation of the parts. It is quite true that errors in diet, and especially errors in diet during the very early days of life, may produce symptoms which we commonly call indigestion, but it must be remembered that these symptoms may be perpetuated as bad habits long after the cause which provoked them has ceased to exist. And thus it comes about that the series of mistakes in diagnosis and treatment which I propose to chronicle in this lecture will be mainly concerned with symptoms which, though originally produced by faulty methods of feeding, were wrongly ascribed to defects in the food and were wrongly treated by changes and alteration in the diet. There is only one cure for faulty habits of this kind, and that is re-education.

Very shortly after I was qualified I had the good fortune to see a case which was then going the round of the children specialists. It was a case of intractable vomiting in a very young baby, the cause of which was as obscure as the treatment adopted was unsuccessful. Everybody who saw the case suggested as a basis of treatment some radical change in the character of the food. In spite, however, of unremitting attention the infant died when about six weeks old. At the necropsy the œsophagus was found to be enormously dilated with irregular thickenings of the muscles. At its junction with the stomach the muscles were extremely hypertrophied, and the lumen showed a marked degree of atresia. In many respects the dilated œsophagus with its sacculations and thickenings had analogies with the conditions we find in cases of congenital dilatation of the colon, or Hirschsprung's disease. Whether in this particular case the dilatations of the œsophagus were of congenital origin, or whether they were secondarily acquired as the result of spasm of the cardia or incoördination of the neuro-muscular mechanism concerned in the propulsion of food down the gullet, will never be known; but reviewing the whole history of the case as I now remember it I cannot help inclining to the view that this was a case of cardiospasm in an extreme form.

Of recent years attention has been directed both by Lust[2] and Aschenheim[3] to a condition in infants which has been called "rumination," and in which a very intractable form of regurgitation or vomiting persists. It is supposed to be due to some abnormal or perverted coördination of the neuro-muscular mechanisms of the œsophagus. I have seen one or two cases which I now conclude were examples of this kind of rumination, but which at the time I did not recognise as such. Further, I am disposed to think that the essential pathogenesis of cases of rumination such as those described by Lust and Aschenheim, as well as of cases of Hirschsprung's disease, and of the case of dilatation of the œsophagus already referred to, is of a comparable, if not of an identical character in each instance—that is to say, that all these conditions are due to ill-coördinated muscular functions. I cannot understand otherwise how it can be that such marked hypertrophy can coexist with such marked dilatation. It seems to me that nothing else than persistent spasms in certain sections or areas can account for the hypertrophy in one part and the dilatation in another. I believe that cases of cardiospasm in infants are much more common than is generally supposed, and that the few published cases in no way represent the true frequency of the condition. I am sure they are seldom diagnosed, and I now feel sure I have missed many myself.

---

[2] Brit. Med. Jour., vol. i., p. 616, 1910.

[1] An abstract of a lecture delivered at the Medical Graduates' College and Polyclinic, Chenies-street, London, W.C., on Feb. 19th, 1914.

[2] Monatschrift für Kinderheilkunde, 1911, vol. x., No. 6.

[3] Zeitschrift für Kinderheilkunde, 1913, vol. viii., p. 161.

Some little time ago I showed,[4] with Mr. Douglas Drew, at the Section for the Study of Disease in Children of the Royal Society of Medicine, a case which we then supposed to be one of congenital stricture of the distal end of the œsophagus. Subsequent events, however, proved that the stricture was probably functional, and not organic in nature, for Mr. Drew succeeded without any difficulty in dilating up the lower end of the œsophagus, and since then the infant has been able to swallow solids with ease, and the symptoms have practically disappeared.

Intractable vomiting is by no means uncommon in infants, and it may be due to obstruction to the onward flow of the food current at any point in the alimentary canal. The obstruction may be due to persistent muscular spasms or to other causes; but certainly, in my experience, pyloric spasm is one of the commonest causes, if not the most common, of vomiting of this kind. The difficulty of making a correct diagnosis in the days when we had no X rays was very considerable; but now, with the aid of a bismuth meal and the X ray screen, the detection of the exact point at which obstruction occurs is easy and accurate.

At the present time so much attention is given to pyloric stenosis, whether of the congenital or acquired type, that there is small risk of the condition escaping notice; indeed, in my judgment, it is diagnosed, and cures claimed, far more frequently than is justified by events. I remember the time, however, when no mention of the condition appeared in the text-books, and when its very existence was known only to a few individuals. The first case I saw was in the year 1895, when my old teacher, the late Dr. W. B. Cheadle, asked me to look after a case of his which was suffering from persistent and violent vomiting. Although we both recognised that the symptoms were due to obstruction in the neighbourhood of the pylorus, owing to the waves of contraction which passed from left to right across a greatly dilated stomach, and which were quite obvious to the naked eye, neither of us suspected hypertrophic pyloric stenosis during life, nor at the necropsy did we recognise that the condition was one of extreme interest and rarity. Mr. Jackson Clarke, then pathologist at St. Mary's Hospital, examined the specimen, and reported that the fusiform tumour which surrounded the pyloric orifice was not a neoplasm, but consisted of hypertrophied muscles only. Some years later (1897) I read an account of the disease,[5] written by Dr. H. Ashby, of Manchester, which induced me to inquire into the literature of the condition. I subsequently published my account of this case in the *Archives of Pediatrics*.[6] Placed in its chronological order, our case was the twenty-fourth to be described, but since that time an enormous number of cases have been recorded and a great literature has grown up round the subject.

Now, passing from symptoms due to incoördination of the neuro-muscular mechanisms of the upper reaches of the alimentary canal, concerning which mistakes in diagnosis are often made, to symptoms connected with the motor functions of the large and small intestine, I would preface my observations by saying that mistakes in the diagnosis of such conditions usually arise in connexion with one or other of the following symptoms: (1) diarrhœa, (2) constipation, and (3) colicky pains.

1. *Diarrhœa.*—This is often wrongly attributed to some indigestible quality of the food, when the true explanation is hypersensitiveness of the neuro-muscular mechanism concerned in the locomotion of food through the intestinal canal, a condition commonly known as lienteric diarrhœa. I see many cases of this kind in which change after change in the character and quantity of the food leaves the infant in exactly the same condition. In such cases a vicious and intractable reflex has been acquired which can only be cured by patient attempts at re-education.

I see many cases of diarrhœa with so-called undigested curds in the motions which are regarded as due to indigestion, but which are in fact due to starvation. Frequent dejections of this kind are often associated with debility which is due to inanition, for in starvation the mucous membrane of the bowel manifests, as it were, a paralytic secretion with frequent alvine discharges which to the inexperienced at once suggest some irritation due to food causes. The presence of so-called undigested curds in the motions is usually the misleading evidence on which the diagnosis is based. I have repeatedly demonstrated, by means of the "test-feed," that infants passing stools of this character are the victims of inanition, and that so far from obtaining food which disagrees, they obtain, as a matter of fact, no milk at all, or only a very small quantity, from the mother's breast. Even the fact that these so-called undigested curds of casein continue to appear in the motions when all milk is withdrawn from the diet, and when the infant only subsists on whey, egg water, or even water, does not appear to suggest to the sceptically minded that they have no more connexion with coagulated casein than they have with hard-boiled white of egg or any other substance with which they have a superficial resemblance. To prove their origin these so-called curds have been submitted to chemical analysis, and even to bio-chemical tests. They are known to contain considerable quantities of fatty acids, mostly in combination with calcium, forming in fact insoluble soaps. Further, they contain a small proportion of albumin, and a remainder which is of uncertain chemical composition but containing nitrogen in relatively the same proportion as occurs in casein. On this evidence, and on the evidence of the superficial appearance to small curds of coagulated casein, these white bodies have been regarded as the undigested remains of milk. But if a stool consisting mainly of these so-called curds is carefully washed out in a bowl of water and the little white balls are teased out and disentangled, they will be found to consist of coiled-up plaques of mucus, which when floated out in the water cannot possibly be mistaken for milk curds or anything else except mucus. The fact that soaps, fatty acids, albumin, bacteria, and calcium salts can be detected in these little white balls by chemical analysis in no way weakens the argument that they are the pathological products of the activity of the mucous membrane, and not the undigested remains of milk, for on similar evidence the mucous discharges from the nose or respiratory tract might be considered of milk origin, for their chemical analysis is the same.

[4] Proceedings of the Royal Society of Medicine, Section for the Study of Disease in Children, 1913, 33.

[5] Archives of Pediatrics, 1897, p. 493.

[6] 1900, p. 241.

I do not mean to imply, by the somewhat dogmatic statements above expressed, that milk residues do not at times appear in the stools and especially in cases of lienteric diarrhœa. What I mean is that these small white particles, generally about the size of a pea, which look like pieces of coagulated milk, and which are found in the stools of infants suffering from colicky pains, are really pieces of stringy mucus which have become partially inspissated and coiled up into tight balls by the peristaltic movements of the bowel. By teasing out and unravelling these little balls it is open to all to convince themselves of the truth of my contention. Further, such conditions, when treated on the ground that they are undigested milk, do not improve.

Diarrhœa, or at least the too frequent passage of dejections, is often attributed to some fault in the character of the food, when the true etiological explanation is that the hypersensitive neuro-muscular mechanisms of the bowel are stimulated into activity by some preceding event—as, for instance, by forcible sucking at a relatively dry breast or at some artificial nipple which is pierced with too small a hole. It must be remembered that although the locomotion of food through the alimentary tract is generally regarded as consisting of a number of independent phases, such as deglutition, intestinal peristalsis, or defæcation; nevertheless each independent neuro-muscular mechanism, whether it be of œsophagus, stomach, or intestine, is closely associated and bound up in a definite and correlated series, action or cessation of action in the one being the liberating stimulus for activity in the next. Thus violent sucking often initiates painful peristalsis or even lienteric diarrhœa, but such diarrhœa is not satisfactorily dealt with by changes in the character of the food.

2. *Constipation.*—Turning now to constipation as a symptom which is often, in an etiological sense, wrongly interpreted and wrongly treated, I may say that there are three common causes of constipation in infants, although the number of occasional causes is almost infinite. The common causes are: (1) dulling or disorganisation of the rectal reflex by previous over-stimulation and exhaustion of the nerve centres (purgative medicines, enemata, suppositories, and previously existing diarrhœas); (2) over-feeding, especially with fat; and (3) underfeeding (chiefly in the case of breast-fed infants). Inasmuch as these causes are in their etiology as widely separated as the poles, it is clearly most irrational to expect that constipation can be treated by any one uniform method—as, for instance, by the administration of castor oil, grey powders, or by increasing the percentage of the fat in the food.

Before we attempt to treat constipation we must discover the cause. I have certain stock questions with which I ply the mother in order to elucidate the actual cause of the constipation. They are as follows: 1. Are the motions hard or soft? 2. Are they large or small? 3. What remedies have you tried? 4. What food and how much have you been giving the baby? By means of these questions I can generally discover whether the rectal reflex has been *tampered* with by injudicious methods of stimulation, also whether the infant has been obtaining *too much* or *too little* food. If the variety of constipation does not fall under any of these headings I search for other causes.

As regards treatment, the cure of cases of constipation due to dislocation of the normal rectal reflex can only be effected by re-education—often a difficult matter and best promoted by massage and the teaching of a new reflex. This should be applied with absolute regularity every day.

Constipation due to excess of fat must be treated by a reduction in the percentage of cream in the case of artificially fed infants and by controlling the quantity of milk consumed in the case of breast-fed infants or possibly by dieting the mother. Formerly I used to treat a number of infants suffering from this variety of constipation by the routine administration of olive oil. Olive oil is of course invaluable in cases in which the infant is suffering from fat starvation, but it only aggravates the condition in the class of case I am now referring to. It was in consequence of the realisation of this mistake that I came to use petroleum as a lubricant in place of olive oil, and since this discovery, now some eight years ago, I have practically used no other form of aperient.

Cases of constipation due to starvation very seldom come under my notice in artificially fed infants, but they are very common among breast-fed infants of the lower classes. I could give details of dozens of cases which have been brought to my clinics, and which have previously been treated ineffectually with aperients and purgatives, but which have immediately improved when the want of food had been corrected.

3. *Colicky pains.*—Finally, I would say a few words about that common symptom of disturbed motor-function which is so often wrongly ascribed to food causes—namely, colic or wind. So-called colic or wind in infants is nearly always due to some spasm of sphincter or group of intestinal muscles which interferes with the normal locomotion of food through the alimentary system. Wind may indeed be actually retained in the stomach by spasm of the cardiac sphincter, but much more often the pain which is supposed to be due to wind is attributable to the arrest in spasm of the normal waves of contraction which pursue one another throughout the whole length of the intestine. The application of the bismuth meal and the X ray screen has revealed some very interesting examples of enterospasm in infants, which has produced troublesome symptoms the nature of which was not altogether clear. One of these cases was as follows: an infant at the Nursery Training School in Hackney had repeated attacks of screaming with serious and violent vomiting. The child was doing badly and losing weight. One day I happened to be at the school when one of these attacks was in progress, and chancing to place my hand on the abdomen I felt some very forcible waves of contraction passing across the upper part of the abdomen. As some of the symptoms were not altogether inconsistent with pyloric spasm, I admitted the infant into the Queen's Hospital and thoroughly investigated the case by means of bismuth feeds and X ray examination. When given a feed of thin

Benger's food thickened with 2 oz. of carbonate of bismuth the infant seemed in less pain and almost ceased vomiting. The interesting fact, however, was that the food, instead of experiencing a check at the pyloric valve, passed through this aperture unusually quickly, and continued to travel down the small intestine and through the ileo-cæcal valve in a perfectly normal manner and at a perfectly normal rate, but when after some six hours it reached the splenic flexure, here it appeared to encounter an unexpected check and the bowel wall lapsed into a condition of somewhat prolonged spasm. From this time forward the locomotion of the bowel contents was irregular, jerky, and spasmodic. Owing to this discovery, and taking advantage of the benefit which the large doses of bismuth seemed to confer on the child, I continued to give very large doses of bismuth combined with petroleum before each meal. The improvement in the infant was immediate; it at once began to put on weight, and within 14 days was returned to the school in a greatly improved condition from which it has not up to date relapsed. Bismuth combined with petroleum seems to exercise almost a charm on disordered peristaltic movements. This case appears to me to be instructive because it illustrates my point that symptoms which are really due to disturbances of the motor function of the bowel can easily be mistaken for symptoms due to inappropriate food, and as such be ineffectively treated. This particular case had been treated for weeks by modifications in the diet and by drugs directed to soothe the irritability of the stomach.

If I have given undue attention to the consideration of the diagnosis and treatment of symptoms referable to disturbances of the motor functions of the alimentary canal as distinguished from those connected with the actual digestion of food it is not because I belittle the importance of dietetics in the prevention and cure of such accidents. I recognise very fully indeed that in the first place these perverted motor functions are produced by wrong methods of feeding, often during the first few days of life. It is very easy to teach impressionable nerve centres incorrect or perverted reflexes which may have most disastrous results. To these perverted reflexes Pawlow has given the name *Bedingungsreflexe*, which may be translated as conditional or facultative reflexes; but by whatever name they are known I am sure that they play a leading rôle in the production of such conditions as rumination in infants, pyloric spasm, enterospasm, constipation, and even diarrhœa. They can only be cured by methods of re-education. It is consequently of the greatest importance to be able to distinguish symptoms which are due to defective digestion proper from those which are due to perverted reflexes, learned, perhaps, a long time previously, and for which at the time being there may be, in an etiological sense, no dietetic basis.

Harley-street, W.

ASYLUM WORKERS' ASSOCIATION.—The annual general meeting of this association will be held at 11, Chandos-street, Cavendish-square, W., on Wednesday, May 20th. The chair will be taken at 3 P.M. by the President, Sir John Jardine. The annual report will be submitted, officers elected, and presentations will be made of medals for long and meritorious nursing service. Matters of much importance to asylum workers will be discussed, and it is hoped that there will be a representative gathering of members and friends of the association.

A CASE OF SUB-TOTAL GASTRECTOMY
PERFORMED FOR CANCER OF THE STOMACH FIVE YEARS AGO.

BY C. MANSELL MOULLIN, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE LONDON HOSPITAL.

IN May, 1909, five years ago, I was asked by Mr. F. Gordon Brown, of Finsbury-circus, to see, in consultation with him, a patient who had been suffering from epigastric pain accompanied by sickness for upwards of two years. She was 51 years of age and rather stout, though she had lost a stone in weight recently. The pain, which was very severe and never really left her, was referred to the mid-sternal region. Food relieved it but not completely. The vomiting had been growing more and more frequent. At first it consisted only of a watery fluid, but for some months past the fluid, towards the end, had been stained a reddish brown. Food was hardly ever returned. There was no history of melæna, but no examination of the fæces was made.

On examining the abdomen there was a tender area to the left of the middle line in the epigastric region, and once or twice an ill-defined, deep-seated hardness was felt there. No enlarged glands could be found. The patient had been for some time restricted to a diet of milk and lime-water with some relief, both as to pain and vomiting. A very guarded prognosis was given, chiefly because of the persistence and severity of the pain.

The operation was performed at St. Thomas's Home on May 8th, Dr. A. P. Gibbons and Dr. A. B. Howitt being present. The abdomen was opened in the middle line and a hard mass was felt at once in the wall of the stomach close to, but not apparently involving the pylorus. There were some enlarged glands along the greater curvature, but as there were no adhesions of any importance it was determined to excise all the affected portion. The gastro-hepatic and the great omentum were cut through and sutured, and the duodenum divided and closed. An incision was then made across the stomach, running from the right side of the œsophagus downwards and slightly to the left, so as to remove the whole of the stomach except a small portion at the cardiac end. The upper portion of this incision was closed with a double row of sutures; the lower end was sutured to the edges of an incision of corresponding length in the jejunum, so as to form a gastrojejunostomy. Two pints of saline were given subcutaneously during the operation, and five more partly subcutaneously, partly by the rectum, in the course of the next 24 hours. The patient was sick once 48 hours after the operation, bringing up some bile, but in other respects recovery was quite uneventful. She left the home on June 9th able to take ordinary light diet. By September she had regained her weight and was able to take all ordinary food without discomfort. Since then she has continued perfectly well and has resumed her work, leading a very active life.

The portion of stomach removed was sent to the Museum of the Royal College of Surgeons of England. There was a characteristic carcinomatous growth originating on the margin of an old chronic ulcer. Recurrence, of course, may take place yet, not along the lines of the incisions, but possibly in some outlying glands, or even in the liver. I have known carcinoma develop in supraclavicular glands as long as 14 years after the removal of the corresponding mamma. There can be no question, therefore, that carcinomatous cells may lie latent for years until circumstances become favourable to their growth. But with this proviso, the operation may be said to have cured the patient, so far as any operation can cure a patient of cancer.

What proportion of cases of chronic ulcer of the stomach end by becoming carcinomatous is uncertain. That a very large number of cases of carcinoma of the stomach originate in chronic ulcers is not uncertain; and considering the ease of the operation (if the ulcer has not been left too long already so that it has eaten into the pancreas or other neighbouring organs), the good prospect of recovery, and the impossibility of deciding at the time whether the induration around a chronic ulcer is purely inflammatory, or malignant, or both, I believe that recovery would be as frequent, and that the subsequent standard of health would be higher and the duration of life longer if partial gastrectomy were performed in such cases instead of simple gastro-enterostomy. It is true the induration around a chronic ulcer sometimes disappears in a marvellous way after an operation, but in nearly all the cases in which this has been recorded there has been a recent attack of acute inflammation, often associated with perforation, grafted upon the old ulcer, and the induration has been largely due to this. The chronic ulcers to which I refer, and for which I consider partial gastrectomy to be preferable, are distinguished by their sharply defined and circumscribed outline. Induration such as this does not disappear, and is only too likely to become the seat of malignant disease. Complete removal ensures that the ulcer will cause no further trouble, and practically abolishes the risk of cancer.

Wimpole-street, W.

A PEDUNCULATED INTRABRONCHIAL TUMOUR (SARCOMA) CAUSING BRONCHIECTASIS.[1]

BY J. A. BRAXTON HICKS, M.D. LOND., M.R.C.P. LOND., D.P.H.,

ASSISTANT PATHOLOGIST TO WESTMINSTER HOSPITAL, ETC.

THE patient, aged 33, complained of cough, profuse expectoration, and occasional blood-spitting. Her family and personal history were unimportant, there being no history of tuberculosis or cancer in her immediate relatives. At the age of 20 she became a nurse at the Cheyne Hospital, Chelsea, and she had to leave there in 1900 on account of a "severe attack of anæmia." She next became a school nurse under the Poor-law authorities at Parsons Green, Sutton, and Hanwell. At Parsons Green she had a transient attack of pleurisy; at Hanwell she had her first attack of hæmoptysis. She then left off nursing and became first an out-patient and then an in-patient of the Brompton Hospital. Next she was an out-patient and in-patient of the Mount Vernon Hospital, and later entered the Hampstead and Northwood Sanatorium. During this time she had had numerous slight attacks of hæmoptysis. but while at Northwood she had such a severe attack that her life was despaired of, although she eventually recovered. In 1902 she was for a while a private patient of Dr. F. T. Hebb, to whom I am indebted for the notes of the early stages of her illness. Her condition for the next eight years was variable, but slowly downhill, and in May, 1910, she was admitted to the Westminster Hospital under the care of Dr. R. G. Hebb, to whom I am much indebted for permission to publish the case.

On admission she was thin and pale. The skin was moist, the legs œdematous, and the fingers "clubbed." Both knee-joints were much swollen and slightly painful. The temperature varied between 96° and 99° F. daily. She had repeated fits of coughing with copious expectoration of purulent sputum. This sputum contained streptococci, pneumococci, and M. catarrhalis, but tubercle bacilli were not found after the most thorough search. It is worthy of note here that tubercle bacilli never had been found in the sputum when examined at the Brompton or Mount Vernon Hospitals or the Northwood Sanatorium. On examination of the chest the right side was seen to be sunken in and to move badly on respiration. Vocal fremitus was increased all over the right side, which was quite dull on percussion. All sorts of added sounds could be heard on auscultation, and at times well-marked amphoric breathing could be made out, *but not always.* Vocal resonance was increased. The larynx showed some slight interarytenoid thickening, but was otherwise normal. The liver and spleen were thought to be slightly enlarged, and the urine contained 0·1 per cent. of albumin and numerous hyaline casts. The fluid from her swollen knee-joints was examined and found to be sterile. The diagnosis of bronchiectasis was made, and this was admirably confirmed by a radiograph taken by Mr. E. S. Worrall, which showed cavitation of the entire right lower lobe. She was treated by the ordinary remedies for bronchiectasis, and in addition an autogenous vaccine was prepared from her sputum. She was discharged in August *in statu quo.*

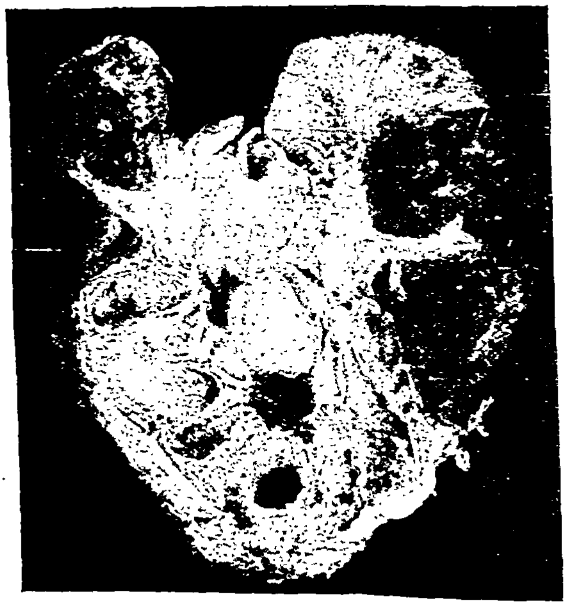
The patient was readmitted in January, 1911, her general condition being somewhat worse, but her physical signs as before. The case appearing suitable for an attempt at drainage of the lung by surgical means, and the operation being agreed to by the patient, Mr. Rock Carling successfully opened and drained the lung on March 8th. The opening was made as low as possible, portions of the eighth and ninth ribs being removed; the lung was carefully stitched to the parietal pleura and chest wall and then opened with a cautery and the bronchiectatic cavities entered. A tube and some gauze were used for drainage. After the operation she did well and seemed to improve for 12 days, but suddenly on March 20th she had a severe hæmoptysis and died rapidly within ten minutes. This hæmoptysis was the only attack she had had while under observation at Westminster Hospital.

Necropsy.—The body was emaciated and pale. Surgical wound in right scapular line 2 inches long, and portions of the eighth and ninth ribs missing here. This wound led into the lower lobe of the right lung, which was bound to the chest wall by old adhesions and recent surgical sutures. The right pleural cavity was dry. The right lower lobe contained four obliquely placed cavities situated midway between the anterior and posterior surfaces of the lobe. These cavities communicated with one another, the lowest draining by the surgical wound, and the highest opened into the main bronchus to the lower lobe. These four cavities were filled with clot and débris. In the right bronchus, 1 inch from the bifurcation and just above the highest of the four cavities just mentioned, was a pedunculated tumour about the size of a walnut. This tumour was attached by a short pedicle to the wall of the bronchus, and on cross section was seen to be of firm consistency with patches of softening scattered about it. The colour of the tumour was white, the softened areas being somewhat more yellow than the rest. The left lung was voluminous and contained inhaled blood. The stomach contained blood. The kidneys, spleen, and liver showed amyloid degeneration, and in addition the liver showed numbers of small hard white secondary deposits of the size of a large pin's head to that of a pea. These were scattered throughout the liver substance, but more so at the periphery than in the deeper parts. There was nothing else noteworthy about the viscera.

---

[1] A paper read before the Medical Section of the Royal Society of Medicine, April 28th, 1914.

Histological examination.—The tumour was seen to be covered partly by columnar epithelium and partly by squamous epithelium (metaplasia). In places the epithelium is much degenerated. The tumour itself is divided into loculi by fibrous bands, which in places are of considerable thickness; these loculi are filled by small round and cuboidal cells, the nuclei of which are round, and though small are relatively large when compared with the cell. In places the tumour is very vascular, and there are large areas of degeneration in several parts (? caused by hæmorrhage into the growth). In some situations the arrangement of the cells is adenomatous, and therefore might by some be classed as a carcinoma. The cells, however, are of mesoblastic type, and it would be more correct to class it as a mesothelioma (adenosarcoma), the histology closely resembling those appearances seen in tumours of supposed congenital origin. The secondary deposits have a similar structure, but no degeneration is visible.



The right lung bisected to show a pedunculated tumour in the bronchus. Four cavities are also seen in the base of the lung, and a surgical drainage hole at the lowest point.

Remarks.—The points of interest in the case are: (1) the rarity of the condition; (2) the impossibility of diagnosing the condition except with the bronchoscope: (3) the slow growth of the tumour and the long history; (4) the intermittent occurrence of amphoric breathing, doubtless due to movements of the tumour in the bronchus; and (5) the mode of termination by ? hæmorrhage from the growth. As regards the mode of termination and the difficulties of diagnosis it is interesting to compare this case with two cases of pedunculated tumour of the stomach that Dr. Gossage and myself showed in November, 1913.[2] In both these stomach cases the mode of termination was by hæmorrhage from the growth, which also showed extensive areas of degeneration as in the case under discussion.

Wimpole-street, W.

A CONSIDERATION OF SOME CASES OF EXOPHTHALMIC GOITRE TREATED BY OPERATION.

By ALBERT J. WALTON, M.S., B.Sc. Lond., F.R.C.S. Eng.,

ASSISTANT SURGEON TO THE LONDON HOSPITAL.

Of late years evidence has been accumulating as to the value of surgical treatment in cases of Graves's disease. This line of treatment is theoretically indicated owing to the evidence that has been brought forward in support of the following conclusions.

1. *That the Disease is Due to an Excess of Thyroid Secretion.*

Unless there is strong evidence that the symptoms are produced by over-activity of the thyroid body there would be theoretically but little indication for the removal of a portion of the gland. Evidence in favour of this theory has been sought for along two lines.

(*a*) *Experiments performed upon animals.*—Edmunds[4] and French[5] have shown that if animals such as monkeys, dogs, and rats be injected with an extract of human goitres the disease could be produced in them. It is true that Klose[10 11] and Carlson[1] have also deduced from experiments that the disease is due to an alteration in rather than an excess of secretion of the thyroid. Such experiments upon animals are, however, of very doubtful value, for it is uncertain what effect a heterogeneous extract prepared from human beings could have upon an animal of an entirely different species.

(*b*) *Clinical evidence.*—Several cases have been reported where large doses of thyroid extract have been taken and have given rise to the symptoms of exophthalmic goitre. In the case described by Von Notthaft,[22] a man took excessive doses as a cure for obesity and rapidly developed the disease. When the extract was discontinued he recovered. In a larger number of recorded cases the administration of thyroid extract in cases of simple enlargement of the gland has been followed by the onset of symptoms of Graves's disease. In all cases of exophthalmic goitre there is evidence of overgrowth of the thyroid gland, although in rare cases such an overgrowth cannot be demonstrated clinically. The nature of the overgrowth is very constant, and consists of a cellular hyperplasia suggesting that the gland is hyper-active. In addition to the above changes it is not uncommon to find a certain amount of hyperthyroidism in association with localised overgrowths of the thyroid, although it is rare for such symptoms to constitute a true case of exophthalmic goitre. These symptoms of hyperthyroidism may occur with adenomata, with primary carcinoma, and even, as recorded by Mori,[21] with secondary growths. The above facts afford strong evidence in favour of the disease being due to over-activity of the thyroid gland.

---

[2] A. M. Gossage and Braxton Hicks: Proceedings of Royal Society of Medicine, 1913 (Medical Section), vol. vii., No. 2.

2. *That the Results of Medical Treatment are Unsatisfactory.*

If these cases reacted well to medical treatment surgical interference would of course be unnecessary, in spite of the fact that the condition is dependent upon an overgrowth of the thyroid. There is, however, increasing evidence that medical treatment is not altogether satisfactory, and is associated not uncommonly with a high mortality. Attention is also being directed to the important fact that medical treatment is often slow, so that even if the disease be ultimately cured the patient may have suffered several years' incapacity.

As regards the mortality, Mackenzie[17] states that in his experience about 25 per cent. of the patients died directly from the disease, whilst Leedham-Green,[15] from a large number of collected cases, gives the mortality under medical treatment as more than 15 per cent. On the other hand, Hale White[8] investigated the cases treated in Guy's Hospital during a period of 20 years. Of over 200 cases 102 alone were traced. Of these 15 had died. He estimated that in a similar number of normal people there would be in the same period of time 8 deaths—that is to say, the mortality in cases of exophthalmic goitre is roughly double that of normal people. Although this death-rate does not seem high, it must be remembered that in the first place only 50 per cent. of the cases were traced, and since it is probable that one of the reasons of the failure to trace the remaining numbers is the fact that many were dead, it seems only fair to assume that these figures under-estimate the mortality. In the second place, these figures do not include 18 patients who died in hospital, these alone giving a mortality of 9 per cent. The above set of figures are sufficient to show that the mortality of the disease is relatively high.

Of equal or even more importance is the length of time during which these patients are incapacitated while under medical treatment. It is being more frequently recognised that the majority of cases are invalided for a very considerable period, and some of them are indeed totally unfitted for work for many years, or even for the rest of their lives. Thus Mackenzie[16] collected 33 of his own patients where the disease lasted five years or ended fatally, and Kuttner[14] traced 9 cases which had been under medical treatment for 15 years. In my own 10 cases 5 of them had had the disease and had been prevented from participating in any active work for a period of two years. It would seem therefore that, in addition to a relatively high mortality, treatment by medical means is very often extremely prolonged.

3. *That the Operative Mortality is not Necessarily High.*

Until the last few years it had been widely believed that the operative mortality in this condition was extremely high, so high, in fact, that many regarded the operation as unjustifiable. The figures of Kocher,[13] Dunhill,[2] and C. H. Mayo[19] have done much to dispel these fears. Kocher,[12] in a series of 865 operations, has reported a total mortality of under 3 per cent Dunhill[2] has only had 4 deaths in 230 cases, and Mayo[19] has had a series of 278 cases without a single death. In my own series of 10 cases, which were all well-marked examples of the disease, there has been no mortality, and at no time had there been any fear of a fatal termination, although several of the cases showed a well-marked reaction to operation.

4. *That the Results of Surgical Treatment are Very Satisfactory.*

In considering the end results of surgical treatment account must be taken not only of the operative mortality but also of the mortality due to the disease in those who recover from the operation. The sum of these figures must be compared with the number of deaths from medical treatment, and operation only advised if the surgical results show a distinct improvement on the medical. The second factor of importance is the length of time for which the patient is incapacitated after operation as compared with the incapacity associated with medical treatment. Kocher[13] found that of his 669 cases 22 died at a later date. Five of these died from some heart condition which was possibly dependent upon the presence of the goitre. In the majority of recorded lists either no note is made of a late post-operative mortality or the figures show that there was no such mortality. As a general rule the reaction from surgical treatment is prompt and a large proportion are permanently cured. Fuller[6] found that 85 per cent. of the 600 cases he collected were completely cured and the relief was prompt. In my own cases, although so short a time has elapsed, one is completely cured and the remainder with the exception of one case are greatly relieved. With regard to the single exception, the patient is better than before operation, but owing probably to the fact that she had to return to relatively hard work shortly after operation she has not yet made as favourable progress as the other cases.

5. *That the Danger of Post-operative Myxœdema is Slight.*

It is frequently asserted that, since in a certain number of cases the thyroid returns to its normal condition after a given interval, some of those cases in whom operation has been performed will in the same period of time develop myxœdema, the remaining portion of the thyroid having returned to its normal state and giving insufficient secretion. I can find, however, no evidence in medical literature that such cases do arise. Fuller[6] states that in the cases he collected a few which showed improvement immediately went on to athyroidism, but no further details of the symptoms are given, and it is probable that these were examples of the rapid onset of myxœdema due to the fact that too much thyroid tissue had been removed at operation, there being several such cases recorded by other surgeons. Such a condition, however, is due to an error of technique and cannot be regarded as an objection to the operation carefully performed.

Details of Present Cases.

In the last year I have operated upon 10 cases all of which were well-marked examples of Graves's disease. I have not included among them several cases of parenchymatous enlargement or simple adenomata which were associated with mild hyperthyroidism, as it is doubtful whether such cases should be considered even as mild varieties of Graves's disease. The details of these cases both as regards their symptoms and the after-results are given in the appended table. The symptoms have been in existence for periods varying from two

Table giving Details of 10 Cases of Exophthalmic Goitre treated by Operation.

Case.	Age.	Sex.	Married or single.	Duration.	Symptoms.	Operation.	Pathological report.	Anæsthetic.	Result.	End result.
1	47	F.	M.	18 months.	Pulse 130. Palpitations; headaches; marked nervousness; skin moist, sweating; much dyspnœa; exophthalmos; Möbius, von Graefe; tremors; thyroid diffusely enlarged.	Dec. 16th, 1913. Hemithyroidectomy.	Marked cellular hyperplasia; few patches of colloid.	Open ether.	Slight increase first few days.	Feb. 19th, 1914. Scar perfect; no tremors; exophthalmos barely visible; feels in perfect health; does housework with ease.
2	44	F.	M.	5 ,,	Pulse 140. Palpitations; flushings; very nervous; skin moist; dyspnœa; moderate exophthalmos; Möbius, von Graefe, Stellwag, and Joffroy all present; tremors; thyroid, diffuse enlargement; amenorrhœa three months; thyroid thrill.	Dec. 3rd, 1913. Hemithyroidectomy.	Marked cellular hyperplasia, with some colloid.	,,	Slight reaction.	Feb. 25th, 1914. Letter from medical attendant. Nervousness much less; tachycardia and palpitations much less; greatly improved.
3	19	F.	S.	7 ,,	Pulse 130. Very weak and tired; palpitations; very nervous; much sweating; much dyspnœa; extreme exophthalmos; Möbius, von Graefe, Stellwag, and Joffroy all present; tremors; thyroid, diffuse enlargement; thrill and pulsation; three months' medical treatment.	Nov. 26th, 1913. Hemithyroidectomy.	Cellular hyperplasia with colloid hypertrophy.	,,	Considerable reaction; pulse 130 for three days; catamenia three days after operation.	Feb. 26th, 1914. Much improvement for two months; relapsed a little after returning home; had to work; now pulse 100; exophthalmos marked in service.
4	33	F.	M.	2 ,,	Pulse 100. Debility; palpitations; loss of weight; nervous; dyspnœa; sweating; much exophthalmos; von Graefe and Stellwag present; thyroid, diffuse enlargement; catamenia regular; no blood changes.	Nov. 12th, 1913. Hemithyroidectomy.	Diffuse colloid overgrowth.	,,	Considerable reaction; pulse 120; temperature 99·5°; alteration in voice two days.	March 8th, 1914. Much improved; slight dyspnœa; returned to work two months; can do it easily.
5	25	F.	S.	2 years.	Pulse 106. Palpitations; nervous; sweating; dyspnœa; sleeplessness; slight exophthalmos; Möbius, von Graefe, Stellwag, and Joffroy; diffuse thyroid; tremors; three months' medical treatment.	Oct. 22nd, 1913. Hemithyroidectomy.	Cellular hyperplasia with little colloid.	,,	Considerable reaction; temperature 101°; pulse 100; rapid recovery.	March 7th, 1914. Nearly well; slight dyspnœa and exophthalmos; can get about in usual way.
6	27	F.	M.*	2 ,,	Pulse 100. Palpitations; nervous; dyspnœa; sweating; anæmic; exophthalmos; Möbius, Stellwag, and Joffroy present; nervous; diffuse thyroid; blood count, 14·5 per cent. lymphocytes.	Sept. 4th, 1913. Hemithyroidectomy.	Richly cellular overgrowth; no colloid.	,,	Slight reaction; acute appendicitis ten days later.	Nov. 30th, 1912. Much improved; slight palpitations; no tremors.
7	24	F.	M.	2 ,,	Pulse 150. Palpitations; systolic murmur present; heart dilated; very nervous; much sweating; much dyspnœa; marked exophthalmos; Möbius, von Graefe, Stellwag, and Joffroy present; catamenia regular; blood—reds 5,700,000, lymphocytes 17·5 per cent.	Feb. 12th, 1913. Hemithyroidectomy.	Much cellular hyperplasia; slight colloid.	,,	Considerable reaction for two days.	March 10th, 1914. Cured; feels in perfect health; eight months pregnant; not nervous; no tremors or exophthalmos.
8	41	F.	S.	2 ,,	Pulse 112. Weakness; fainting fits; palpitations; nervousness; much sweating; marked dyspnœa; occasional diarrhœa; marked exophthalmos; catamenia regular; Möbius, von Graefe, Stellwag, and Joffroy present; marked tremors; diffuse thyroid; sent home to rest for three weeks before operation.	Jan. 14th, 1914. Hemithyroidectomy; preliminary ligature of inferior thyroid artery.	Richly cellular hyperplasia; small amount of colloid.	Open ether; rectal ether.	Considerable reaction; pulse 100; vomiting two days.	March 5th, 1914. Much better; still dyspnœa and palpitations on exertion; exophthalmos present.
9	23	F.	S.	2 ,,	Pulse 120. Palpitations; very nervous; sweating; dyspnœa; some difficulty in swallowing; occasional diarrhœa; extreme exophthalmos; Möbius, von Graefe, Stellwag, and Joffroy all present; tremors; amenorrhœa; six months' medical treatment; no improvement.	Feb. 18th, 1914. Hemithyroidectomy; preliminary ligature of inferior thyroid artery.	Cellular hyperplasia.	,,	Marked reaction; diarrhœa; vomiting; restlessness; temperature 100°, pulse 140; recovery after three days.	Considerably improved as regards nervousness; too recent.
10	40	F.	S.	7 months.	Pulse 110. Palpitations; very nervous; much sweating; dyspnœa; exophthalmos; Möbius, von Graefe, Stellwag, and Joffroy present; severe diarrhœa; marked tremors; slight dysphagia; brother died from exophthalmic goitre; no operation; one month's medical treatment.	Feb. 18th, 1914. Hemithyroidectomy; preliminary ligature of inferior thyroid artery.	Cellular and colloid hyperplasia.	,,	Marked reaction for two days; temperature 102°.	Much improved; still in on medical side; nervousness less; pulse 90; palpitations less.

* One child.

months to two years, and the pathological changes found were of interest. As Berry[21] has pointed out, there are very few records of the changes found in the early stages. It will be seen from the table that the earlier cases all showed a certain amount, or even an excess, of colloid material,[2] which is suggestive that the primary change is one of colloidal increase. The later cases showed a marked cellular proliferation and the presence of little, if any, colloid material, the pathological changes being therefore in accordance with those usually described with this disease.

Success in operating to a large extent depends upon a careful consideration of the time at which the operation should be performed. There are certain acute cases where the symptoms appear suddenly and progress with great rapidity. In many of these the thyroid shows but little enlargement in the earlier stages. Operation in such cases is associated with a very high mortality, so that this form of treatment should never be advocated.

In the more common varieties of the disease it is very important to realise that the symptoms show very considerable variation in their severity. Not infrequently there are exacerbations which last for a week or more and are followed by periods during which the symptoms are in abeyance. If possible such cases must be watched and operative treatment carried out in one of the intervals between the exacerbations.

Three of my own cases came into hospital with very marked nervousness, rapid pulse, dyspnœa, and tremors. They were all given a period of three weeks' complete rest in bed, at the end of which time the severity of the symptoms was considerably improved and operation was safely carried out. The failure to recognise this fact and the tendency to operate during a period when the symptoms are marked is, in my opinion, largely responsible for the high mortality reported in earlier series of cases.

In addition to this fluctuation in the symptoms the length of time that the disease has existed is also of importance. Plummer[23] has pointed out that the greatest height of intoxication is reached during the latter half of the first year and then rapidly drops, so that operation is more likely to be successful if performed either early in the disease or at a later period, and as far as possible in my own series I have tried to perform the operation either within the first six months or after a period of two years. It will be noted that in one case operation was performed at the eighteenth month of the disease, but in this case, which was carefully kept under observation, it was found that in the relatively quiet intervals the symptoms were comparatively mild. In the later stages of the disease—that is to say, after several years—there is an increase of danger owing to the presence of secondary degeneration in other viscera.

The danger of performing operations on other parts of the body in patients suffering from Graves's disease must also be kept in mind. In such circumstances there is the same stimulation of the thyroid secretion as occurs when the thyroid itself is operated upon, but this is not counterbalanced by the fact that a portion of the thyroid has been removed. If, therefore, an operation has to be performed on some other organ it is always wiser if possible to carry out first the operative treatment on the thyroid and to perform the other operation at a later date.

It will be noticed that one of my cases developed acute appendicitis two weeks after hemithyroidectomy. Operation was unhesitatingly carried out for this condition with no ill-results.

As regards the question of anæsthesia, much difference of opinion has arisen as to whether the operation should be performed under a local or general anæsthetic. On the one hand, Kocher[15] and Dunhill[2] strongly advocate the use of a local anæsthetic, the latter regarding its use as a most important factor in the success of operative treatment. On the other hand, Mayo[20] in the majority of cases prefers open ether.

Personally, I have in every case used a general anæsthetic, open ether being always employed, and I am of the opinion that it is more important to overcome the mental fear which is so marked a factor than to eliminate the slight toxic effect of a general anæsthetic. It is true that in all cases this anæsthetic has been administered by one highly skilled in its use, but in no case has there been the slightest difficulty or trouble. I consider the avoidance of mental excitement to be of so much importance that in the last three cases the patient has not been informed of the date of the operation, and has had this carried out without her knowledge. A solution of ether in olive oil (5 oz. of a 50 per cent. solution) was administered per rectum by the method advocated by Gwathmey[7] 20 minutes before operation. On reaching the theatre the patient was unconscious, and the anæsthetic was then continued with ether on the open mask. The fear of the operation and the disagreeable preliminaries are thus avoided. It is, of course, necessary if such a method be used to obtain the consent and assistance of the relatives.

Operative Details.

As regards the operative details, hemithyroidectomy has been performed in every case, and unless there was some evidence suggesting that the left lobe should be removed a right hemithyroidectomy was the operation of choice. Kocher's horseshoe incision passing over both lobes was used. The two anterior jugular veins being tied and divided, the anterior border of the sterno-mastoid was freed and retracted. The pretracheal muscles were then divided and carefully dissected off the gland. The upper pole was dissected and the vessels ligatured *en masse* and the upper pole freed. The importance of keeping within the capsule and even leaving a small layer of the gland on the posterior surface was fully recognised, thereby safeguarding both the parathyroids and the recurrent laryngeal nerves. The drawback to this method is that in this position the inferior thyroid artery has already divided into its branches. If these be cut separately and then picked up with forceps there is often very free hæmorrhage owing to the marked vascularity of the gland. For this reason I have in the last three cases laid bare the artery just internal to the carotid sheath by separating the fascial planes, as advocated by Jones,[9] and applied a ligature to the artery in its continuity. Even after this preliminary step it is remarkable that a considerable amount of hæmorrhage may occur from the separate branches as they are divided. The whole lobe is then carefully dissected off the trachea and the isthmus divided. Any bleeding points are ligatured; a small tube is inserted into the wound for 24 hours; the muscles sutured with catgut; and the skin with silkworm gut. In spite of many expressions to the contrary it would appear to be of great importance that the gland should be most carefully handled, and in my own cases

I have used great care not to compress the gland in any part of the operation. Each stage should be slowly and carefully performed, so that in the majority of cases the operation will occupy from three-quarters to one hour. In none of my cases was it necessary to perform a preliminary ligature of the vessels. Certain cases have had most marked symptoms, but after a short period of complete rest in bed these had sufficiently abated to allow the operation of hemithyroidectomy to be safely carried out. It is probable, however, that in cases of longer standing such a preliminary form of treatment would be insufficient, and that ligature might have to be carried out some time previous to the hemithyroidectomy.

In most of the cases there was a considerable amount of reaction for the first two days after the operation. The pulse and the temperature both showed a slight rise, and in two of the more severe cases there was a considerable amount of restlessness. To combat this large doses of saline were given per rectum and fluid by the mouth, hypodermic injections of morphia not being restricted.

Weymouth-street, W.

MALIGNANT TUMOURS OF BONES:

A NEW METHOD IN CONSERVATIVE OPERATIVE TREATMENT.

BY PROFESSOR R. WENGLOWSKI,
MOSCOW.

IN malignant tumours which affect bone the surgeon is now compelled to resect the bone. In tumours of the extremities, if the tumour involves the greater part of the bone, amputation is necessary. Generally the resected portion of the bone is replaced by pieces of living or dead bone from the same patient or from some other person. Experiments have shown that the transplanted living bone has generally died and become replaced by new bone, and the same replacement also takes place in the transplantation of pieces of dead bone, but more slowly than when living bone is employed.

To avoid the resection of the affected portion of bone it occurred to me to sterilise the bone and thus to kill all the elements of the tumour, and then to allow the dead bone to remain in its natural connexion with the healthy part of bone. After the sterilisation the bone resembles exactly the piece of dead bone inserted after a resection; it is covered with the soft parts and the wound is treated in the same way. In fact, in this method the bone which is killed corresponds to transplanted bone. The chief advantage of the method consists in the complete and natural connexion of the killed bone with the sound bone, such a connexion as cannot be produced by the most ingenious operation. Moreover, the sterilisation is technically much more simple and easy than the resection and transplantation.

The sterilisation is performed by means of steam under high pressure. For this purpose an ordinary autoclave is used, or even a steam kettle may be employed; in it steam is formed under a pressure of from 3 to 5 atmospheres. Upon the spout of the kettle I put a thick-walled rubber tube from 1½ to 2 metres long, and on the other end of this tube I fasten a piece of metal tubing. This metal piece has many holes for the escape of the steam. I make use of two models: for the sterilisation of the front side of the bone a straight metal tube with terminal holes as in Fig. 1—it gives a direct stream of steam; for the hinder surface of the bone I use a larger flattened tube which is slightly curved, and the concave side has the holes for the escape of the steam. (Fig. 2.)

FIG. 1.

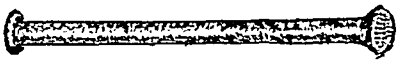

FIG. 2.

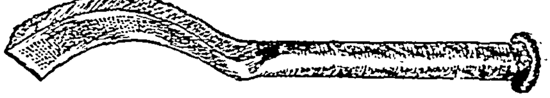

The sterilisation proceeds as follows. After the removal of the tumour in the soft parts I scrape off the rest of the tumour upon the bone and lay bare the bone as for a resection. To protect the soft parts from burning I cover them with three or four thicknesses of gauze; upon this I put a thin sterilised layer of asbestos, and finally a metal plate. This metal plate is used to guard the soft parts from the hot condensation water which might trickle through the gauze and the asbestos. Then the curved metal tube is passed under the bone and the steam is turned on.

I have made the following experiments to determine the time necessary for the sterilisation of the different bones. The femur was sawed through; into its medullary cavity I pushed a thermometer, and I placed the curved metal tube upon the outside of the bone. After from 4 to 4½ minutes the thermometer showed from 75° to 80° C., a temperature not only enough to kill all the cells, but also any bacteria present. Moreover, it appeared that not only the surface near the steam reaches such a temperature, but also the opposite side of the bone. To heat the tibia to from 75° to 80° C. it is necessary to apply the steam for 3 minutes, for the lower jaw-bone 1½ minutes, and for the condyles of the femur 8 minutes. To determine how far the over-heating extends sideways in the direction of the sound bone I put the bulb of the thermometer on the bone at a distance of from 2 to 3 cm. It appeared that at 2 cm. distant the temperature is only 45° to 50° C., and at 3 cm. distant from 35° to 40° C., so that the effect of the steam only extends to about 2 cm. from the steam. If the greater part of the bone is to be sterilised the sterilisation must be effected bit by bit, the metal tube being pushed along the bone. The experiment shows that it is not necessary to sterilise the front surface of the bone by itself, for it is included in the sphere of activity of the steam which has sterilised the medullary cavity.

This method is only an attempt to extend the field of conservatism in the treatment of malignant tumours of bone.

THE INFLUENCE OF THE X RAYS ON SOME CASES OF PERSISTENT SUPPURATION.

By E. P. CUMBERBATCH, B.M. OXON., M.R.C.P. LOND.,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

TWO years ago I tried the effect of the X rays upon a case of chronic suppuration of very long duration, which had resisted other forms of treatment, including surgical operation. The suppuration was arrested, the part healed, and the cure has lasted to the present time. Three other cases of a similar kind were then treated, and equally good results were obtained. During the past year other cases have been treated so as to investigate the action of the X rays upon chronic suppuration, and the results show that this form of treatment has an influence upon its progress, lessening it in some cases, and in others permanently arresting it. Many cases are still under treatment, but a short account will be given of the first four cases, as they have been kept under observation for the longest time.

CASE 1.—A patient aged 22. A case of infective periostitis and prolonged suppuration of three years' duration. The past history showed that in 1904 the patient had had an abscess on her chin; it had healed spontaneously. In 1908 another abscess had appeared in the same situation. It "broke," and began to discharge. The discharge was small in amount but persistent. Early in 1910 a surgical operation was performed, and another in November of the same year, but after each the discharge soon reappeared. In February, 1911, the patient was admitted to hospital, the sinus was excised, the bone scraped, and the wound stitched. In July it was necessary to repeat the operation, as the discharge had recurred. A piece of dead bone was removed and some more was scraped away. In October a fifth operation was carried out, again without any lasting benefit. In December X ray treatment was commenced. There was then a sinus leading down to bone in the region of the symphysis of the lower jaw, with granulations extending for a quarter of an inch around and the outlying skin was adherent. One application of X rays was made in each period of three weeks, full doses being given (tint B, Sabouraud's method of measurement). After the fifth application the discharge greatly diminished; after the eighth it further diminished and became intermittent; and after the eleventh it ceased, and no more was noticed for three months. During this time the skin grew over the granulations, and the closed sinus and the site of the former suppuration was marked by a deep dimple with a small area of red skin at its base. At the end of the three months a slight discharge was again noticed and another application of X rays was made, and one more (the last given) a month later. The discharge ceased altogether, and no more was noticed during the succeeding 15 months. The patient was kept under observation during this time, and was last seen in February, 1914.

CASE 2.—A patient, aged 15. A case of chronic infective periostitis with chronic suppuration lasting six months. Past history: In December, 1911, a painful swelling appeared on the right side of the face over the lower jaw. The skin became red and then "broke," and a purulent discharge made its appearance and continued day after day without cessation. In June, 1912, the patient was taken to hospital. An operation was performed and a piece of dead bone was removed. The discharge soon reappeared. On July 23rd X ray treatment was commenced. There was then a firm swelling to be felt on the body of the lower jaw in the region of the angle, measuring about 1½ inches by ½ inch. The skin overlying was red; and at its centre was a sinus from which pus was oozing. Smaller applications of X rays were given than in Case 1, but at shorter intervals, one each week. After the second application the discharge lessened and became intermittent, and after the third the sinus closed and no more discharge was seen from that time onwards. Three more short applications were made, the last on Sept. 9th. In January, 1913, the swelling had diminished in size, and the skin overlying was slightly erythematous and a little keloid was present in it. In December the swelling could not be felt, and the keloid had disappeared. In March, 1914, a pink scar marked the site of the former suppuration and swelling.

CASE 3.—A patient aged 20. This was a case probably of hygroma which was subsequently infected. Past history: In 1908 the patient noticed a painless swelling on the back of the forearm just above the wrist. It very slowly enlarged. In 1911 the swelling was incised, and a "dark brown" fluid escaped. Soon after, a second swelling, similar to the first, appeared close to it, nearer the elbow. A third swelling also appeared over the wrist, but it disappeared spontaneously. The discharge from the first swelling persisted in spite of local treatment. On April 30th, 1913, X ray treatment was commenced. At that time there was a tense swelling on the posterior aspect of the forearm, about an inch in diameter, slightly movable, and slightly raising the overlying skin, which was normal and not inflamed. This was the second swelling noticed by the patient. Immediately below was a sinus, from the opening of which was oozing a sero-purulent fluid. The bones of the forearm were X rayed and found to be normal. Applications of X rays were made once a fortnight. After the second application the discharge considerably diminished, and after the third it disappeared altogether. One more application was made. In January, 1914, the sinus was still closed. The swelling was still palpable, but it was considerably smaller.

CASE 4.—A patient aged 11. A case of tuberculous bursitis; operation and subsequent chronic discharge. Past history: In January, 1913, the patient developed pain and swelling in front of one knee. In March an abscess in the prepatellar bursa was opened and the cavity scraped out. Tubercle bacilli were found. The wound healed by first intention, but later on it reopened at one point and pus continued to discharge slowly. In July, X ray treatment was commenced. At that time there was a thin sero-purulent discharge from a sinus leading to the prepatellar bursa. There was also clinical evidence of tuberculous infection of the knee-joint. The treatment was repeated once every fortnight. After the second application the discharge diminished, and after the third it disappeared. The patient was afterwards admitted to the Lord Mayor Treloar's Home at Alton. The disease became quiescent in the knee, but there was no more discharge from the former sinus (January, 1914).

These four cases showed chronic suppuration, small in amount, and in superficial situations. Case 1 received full applications of X rays at longer intervals; Case 2 received small applications at short intervals; and Cases 3 and 4 received medium applications at intervals of medium length. The dosage was measured by Sabouraud's method. The most suitable technique with regard to dosage, penetration power of the rays, and the use of filters is difficult to decide, particularly as the *modus operandi* of the X rays in producing their effects on the tissues is not known. In arresting the process of suppuration the X rays do not act only (if at all) by destroying the pyogenic organisms. In some experiments that were made to test the action of the X rays upon cultures of bacteria the pyogenic organisms were not destroyed. I am inclined to the belief that the X rays produce some local tissue reaction against the invading organisms, and at the same time some general reaction. In many of the cases that have been treated there has been considerable improvement in the general health, although in some of them the suppuration has not been arrested.

I am indebted to Mr. D'Arcy Power for permission to publish Case 1.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Clinical Cases and Pathological Specimens.

A MEETING of this section was held on May 8th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. OLIVE RIVIERE showed a case of Spleno-myelogenic Leukæmia. It was that of a boy aged 12, who was admitted to hospital in December, 1913, with history of cough, breathlessness, pain in the right shoulder, and general weakness of one year's duration. He then was well nourished with a somewhat plethoric aspect. The spleen reached to the umbilicus; the liver 1 in. below the costal margin. Signs of enlarged thoracic glands were found mainly consisting of increase of oval interspinous dulness on the right side and impairment at the lung apex. A skiagram confirmed this. The urine contained much albumin. He had been treated by arsenic, X rays, and benzol. During the time the boy had been under observation he had felt well, had gained 6 lb. in weight, and his temperature had kept within normal limits. The pulse was accelerated, about 116. The liver had remained unaltered, but the spleen had increased in size both downwards and forwards. The area of lung impairment, indicative of enlarged chest glands, had also increased, and now extended between the first and ninth dorsal spines on the right side. The leucocytes had increased from 167,000 to 425,000 per c.mm.

Mr. SIDNEY A. BOYD showed a case illustrating the treatment by Splenectomy for Splenomegalic Cirrhosis with Ascites. The woman, aged 23, came under observation in November, 1913, for ascites, for which she had been in hospital in 1908. The notes of the case stated that the spleen was then somewhat enlarged. Paracentesis abdominis was performed several times, but the fluid quickly re-accumulated. Laparotomy was then performed, and the condition was thought to be due to tuberculous peritonitis. There were "some very suspicious caseous masses at the junction of the Fallopian tubes with the uterus, and partly on the broad ligaments. No definite tubercles could be seen elsewhere. The peritoneum looked very red, was much congested, and bled very freely." The abdomen was drained with a rubber tube for 24 hours, a large quantity of fluid escaping. She had made a good recovery from this operation, and remained in good health until October, 1913, when she noticed the abdomen again becoming distended. Upon examination in November, 1913, the patient was found to be a well-nourished young woman, not anæmic nor icteric, and with no signs of disease in the chest. The abdomen was greatly distended, the girth at the umbilicus being 36 in. No dilated veins were visible on the abdominal wall. The scar of the previous operation had stretched somewhat and bulged forwards. The distension was obviously due to ascites, and in the upper part of the abdomen an enlarged spleen could be felt. The liver was not palpable. Eight days later laparotomy was performed, the old scar being excised, and a large quantity of straw-coloured fluid escaped. There were no signs of tuberculosis on the parietal or visceral peritoneum, but a few adhesions were present between the coils of intestine. Except for some adhesions around the pelvic organs the latter appeared normal. The liver felt hard and irregular on the surface and smaller than normal. The spleen was considerably enlarged, and its convex surface was free from adhesions. The parietal peritoneum was somewhat thickened. The incision was closed and healed well in seven days. The Wassermann reaction was negative. The ascites rapidly recurred after the operation. Paracentesis was performed and 15 pints of fluid drawn off. This was repeated, when 11 pints were drawn off. Splenectomy was then performed through a vertical incision at the outer edge of the left rectus. It was not possible to deliver the spleen through the wound on account of a broad band of adhesion from the posterior border to the posterior abdominal wall. The pedicle was therefore first tied off in sections and divided, and the adhesions posteriorly then dealt with. The branches of the splenic artery and vein were very large, but very little blood was lost. The liver was inspected and found to be in an extremely cirrhotic state, being not more than two-thirds the normal size, very hard and granular on the surface. There was practically no omentum present, only a few tags, or omentopexy would have been performed. The incision was closed in the usual way. The patient recovered well from the operation and her convalescence was smooth. The ascitic fluid collected again, but more slowly than before the operation. Three and a half weeks after the operation paracentesis was performed, 11½ pints being drawn off. Eleven days later the girth had increased from re-accumulation of fluid, but after this it gradually decreased and the fluid disappeared. It had *not since* re-collected, and the patient's general condition was good. Dr. A. G. Gibson had cultivated, after 18 days' incubation, a thick Gram-negative, non-motile bacillus which could not be continued in subculture. The remainder of the culture tubes remained sterile. This case was of interest both from the point of view of diagnosis and also from the effect of removal of the spleen. The case was obviously not one of Banti's disease (regarding Banti's disease as the terminal stage of splenic anæmia). There had been no anæmia, no leucopenia, no gastro-intestinal hæmorrhage. The spleen was known to have been enlarged in 1908, when laparotomy was performed for chronic peritonitis, probably of a tuberculous nature. Was it possible that the whole condition was due to tuberculosis—the splenomegaly, the hepatic cirrhosis, and the ascites? (Various French authors had raised the question of tuberculous hepatic cirrhosis.) The first laparotomy cured the ascites for five years. The second laparotomy had no effect on the ascites, which rapidly recurred. Removal of the spleen certainly had a direct effect upon it. The ascites could not have been due solely to perisplenitis, as the fluid re-accumulated at first after removal of the spleen and the abdomen had to be tapped. Nor would simple mechanical relief to the portal circulation, which splenectomy would entail, account for the result for the same reason. Removal of the spleen was *not* likely to influence the hepatic cirrhosis so favourably in a few weeks as to cause the ascites to disappear. On the other hand, if the spleen be regarded as a primary seat of infection by the organism grown from it, secondary to which a chronic peritonitis developed and also hepatic cirrhosis, this was an explanation which would satisfy all the conditions. This was the view which Mr. Boyd was inclined to take, and to consider the illness from which the patient suffered six years ago as an independent one, as far as the ascites was concerned. Time alone would tell whether the removal of the spleen had arrested the progress of the cirrhosis, but from the point of view of relieving the ascites the operation had already justified itself.

Dr. ARTHUR F. HERTZ showed three cases of Thomsen's Disease in members of the same family, two brothers aged 25 and 13, and a sister aged 16. The degree of hypertrophy of the muscles was very marked,

Dr. F. PARKES WEBER showed a case of Progressive Vertebral Ankylosis ("Spondylose Rhizomélique"). The patient was a man aged 67. The whole of the vertebral column and the cranio-vertebral articulations appeared to be ankylosed in a position of kyphosis characteristic of such cases. The ribs apparently did not move with respiration, which was altogether diaphragmatic. He could open his mouth a little. The movement in both shoulders was much limited, more in the right than the left. The hip-joints were severely affected. The more distal joints of his limbs were free, excepting that he could not extend his knees completely. In the semi-recumbent position he could feed himself with a spoon. He could walk about a little with the help of a stick. Some tremulousness of the hands, suggesting that of paralysis agitans, was often observable. Roentgen skiagrams of the patient's neck (lateral view) showed that all the bodies of the vertebræ were united by a layer of bone at their anterior margins. There was no history of any venereal disease, and the blood serum gave a negative Wassermann reaction for syphilis. The teeth and gums were in a very bad condition, with much stone-like incrustation. There was much muscular rigidity or hypertonicity, as if the muscles were "on guard" to shield the joints or prevent sudden "jarring" movements of the body.

Dr. **WEBER** also showed a specimen of Spasmodic Stricture of the Œsophagus (Cardiospasm) with Fusiform Dilatation above it. The patient from whom this specimen was taken was a man aged 80, who had been suffering more or less (on and off) from obstruction in the œsophagus since the latter part of 1904. In February, 1906, he was in a very starved condition, and as no soft bougie could be passed through the cardia into the stomach, Dr. Zum Busch performed a gastrostomy. After the operation the patient improved very much, and the gastrostomy opening was allowed to close. It was completely closed in March, 1908, and it was quite clear that there was no carcinomatous stricture of the œsophagus present, but the old trouble had returned and the patient had to be fed by a hard œsophageal bougie, as at that time no soft bougie could be passed through the cardia. When he left the hospital again in May, 1908, he was feeling well and had gained 13 lb. in weight. In November, 1909, Dr. Zum Busch had again to dilate the cardia on account of spasmodic stricture. Since that time the patient had been an in-patient occasionally on the medical side of the hospital. In April he had two attacks of cardiac syncope, from the latter of which he died. The post-mortem examination showed that the cardia, which did not appear much (if at all) thickened, admitted the passage of the middle finger; yet the stomach was empty, and the œsophagus contained food. There was decided fusiform dilatation of the lower part of the œsophagus. There could scarcely be any doubt that in spite of the characteristic absence (or almost entire absence) of hypertrophy of the cardia the dilatation of the œsophagus was secondary to the cardiospasm. But what the exact cause was of the cardiospasm in the severe and dangerous type of cases, of which the present one was an excellent example, remained a mystery.

The **PRESIDENT** showed a specimen of Cancer of the Rectum; excision after application of radium. It was removed from a man, aged 73, in April last. In October, 1913, there was a typical annular growth, 1½ inches from the anus. A piece of mucous membrane about the breadth of the finger between the two ends of the growth was unaffected. In October, 2 mgm. of radium were applied on five consecutive days for six hours. In November both to the finger and to the eye all appearance of growth had disappeared. There was a complete ring of cicatricial tissue, the free part of the bowel being no longer visible. In February last colostomy was necessary for the relief of symptoms due to the stricture. In April the disease was removed by the perineal route, the proximal end being sutured to the anal portion without division of the sphincter. Complete union of the bowel took place and the colostomy wound was closed a month later. The specimen showed what appeared to be a cicatricial stricture. There was healthy mucous membrane above, whilst below it looked smoother than normal and the muscular coat seemed thickened. Two small hard glands were present in the meso-rectum. Microscopically the typical appearance of a cicatrising cylindrical epithelioma was seen in the section, through the stricture and also in the lymphatics. The whole of the rectum below the stricture, though appearing thickened, did not show any growth. The specimen was exhibited to show the favourable effects of radium.

Mr. T. L. **ELLIS** and Dr. H. D. **ROLLESTON** showed a case of Arthritis associated with Psoriasis. The patient, aged 35, had never had syphilis, gonorrhœa, or rheumatic fever. Twenty years ago he had had left-sided pleurisy, and about the same time he had injured the left knee, but he had no further trouble with it until about four years ago, when it became painful and stiff, psoriasis having appeared one month before. Two years ago he was treated for six months with arsenic, and both the psoriasis and the arthritis disappeared. In November, 1912, the psoriasis and the arthritis gradually recurred, and in April, 1913, he was treated with ionisation without any improvement. Radiography showed slight irregularity of the inner surface and inner condyle of the femur and the head of the tibia near the articular surfaces, thus suggesting slight superficial ostitis. Some carious teeth were removed, and about this time the right knee became affected. In October last he had in addition some stiffness of the temporo-maxillary joints, some more bad teeth were removed, and a vaccine, prepared from streptococci and pneumococci isolated from the sockets, was given with some slight benefit. The psoriasis practically disappeared under arsenic and local treatment (butyl-salicylate was employed as well as the ordinary external applications), but the arthritis did not, as on a former occasion, show a corresponding improvement. The arsenic was discontinued on account of abdominal pain, and the psoriasis was returning. The nails showed the results of psoriasis. Aspiration of the knee and bacteriological examination of the fæces had failed to throw any light on the cause of the arthritis. The urine yielded a diphtheroid organism and a Gram-positive coccus. The temperature had been practically normal throughout. Leucodescent lights and strapping had been employed, and quite recently, in the light of R. Pemberton's conclusions that rheumatoid arthritis was a metabolic disease due to intolerance to ordinary quantities of protein and carbohydrate food, a restricted diet combined with thyroid extract was being tried. The knees were swollen, painful, and stiff.

Dr. **JAMES GALLOWAY** exhibited specimens from a case of Splenomegaly with Gastro-intestinal Hæmorrhages (shown at the meeting of the section on Feb. 13th). The patient was prepared for operation first by the removal of free abdominal fluid—about 30 pints of fluid were drawn off the day before the operation—and by other appropriate measures. The operation of splenectomy was performed in March. The spleen was removed through an incision corresponding to the outer edge of the left rectus muscle. The spleen itself had very few adhesions, but there was a little difficulty in finding and isolating the pedicle. A large thin-walled vessel, no doubt the splenic vein, was ligatured, but a few minutes later the cavity from which the spleen was being removed filled up rapidly with venous blood, probably from the splenic vein. On stopping the hæmorrhage and clearing out the cavity the opening of the splenic vein was seen and more carefully ligatured. The operation in the later stages had to be performed as rapidly as possible on account of the exhaustion of the patient. The immediate result of the operation seemed to be satisfactory. The patient recovered in quite a remarkable way from the shock and the next day the number of red blood cells was found to be 2,300,000. The temperature rose rapidly after the operation, however, and again fell, till four days later it had reached the level of 100° F. Once more a rise of temperature occurred, and along with this there was evidence that a certain portion of the wound was not healing. Quantities of fluid began to flow through the wound from the abdominal cavity, and gradually the greater portion of the wound opened out, much ascitic fluid passing into the dressings. In spite of this condition the patient exhibited remarkable powers of resistance, and it was not till ten days after the operation that he showed definite signs of exhaustion. No signs of general peritonitis were at any time observable; he died from what appeared to be exhaustion 15 days after the operation. Post-mortem examination revealed an infected condition of the external wound and, to a slight extent, of the cavity from which the spleen had been removed in the immediate neighbourhood of the wound, but there were no indications of any widespread or generalised peritoneal infection. The liver was markedly cirrhosed, the cirrhosis being of a coarse, multilobular type. The cut end of the splenic vein at the point of ligature was well healed. The splenic vein itself was enlarged, markedly tortuous, and in parts thrombosed. The remains of the vasa brevia were also enlarged and the veins of the mucous membrane in the lower portion of the œsophagus and the neighbouring part of the stomach were greatly enlarged and congested.

Dr. J. **ALISON GLOVER** read a short paper on a case of Rupture of an Aneurysm of the Abdominal Aorta in a young woman.

SECTION OF OPHTHALMOLOGY.

Pathological Observations on the Filtration Angle in some Glaucoma Cases.—Ideal Glaucoma Incision.—Variable Flap Operation for Chronic Glaucoma.—Herbert's Small-flap Operation for Glaucoma.—Exhibition of Cases and Specimens.

A MEETING of this section was held on May 6th under the presidency of Sir ANDERSON CRITCHETT.

Mr. BASIL T. LANG showed a stereoscopic X ray photograph of a case of Traumatic Enophthalmos; also a bottle specimen showing an early stage in intra-ocular suppuration.

Dr. J. S. BOOKLESS showed a Congenital Cataract, probably of the Coppuc type.

Mr. R. AFFLECK GREEVES read a paper entitled "Pathological Observations on the Filtration Angle in some Glaucoma Cases." He spoke of glaucoma cases in which there was no closure of the filtration angle by a peripheral anterior synechia. The cases described in the paper resolved themselves into three groups. In the first were cases in which an irido-cyclitis was, or had been, present. He described the invasion of the spaces of Fontana by granulation tissue containing capillary vessels, this tissue ultimately forming a solid mass of scar tissue, with which the pectinate ligament became incorporated. In the second group the tissues of the pectinate ligament were unaltered, but the spaces were blocked by large swollen cells, apparently of a phagocytic nature. In the third group the spaces of Fontana were open, but simple retinal detachment was present. In these latter cases the author suggested the rise of tension and the retinal detachment were due to the same cause—namely, an alteration in the composition of the intra-ocular fluid. Mr. Greeves also commented on secondary glaucoma with intra-ocular growth, and said he thought that in some cases an inflammatory element might be present. Microphotographs illustrated the paper, shown by the epidiascope.

Lieutenant-Colonel H. HERBERT, I.M.S., read a paper on the Ideal Glaucoma Incision. He said the section most suitable for the relief of glaucoma was a limited subconjunctival incision in the transverse vertical plane, a millimetre behind the limbus, the conjunctiva at this point being only loosely attached. A sufficiently near approach to this section could be obtained by puncture and counter-puncture with a very narrow tapering knife. Though sufficiently peripheral superficially to facilitate diffusion of aqueous backward under the conjunctiva, it reached, the deep surface of the cornea well in front of the root of the iris. Although making only a limited opening into the anterior chamber the incision was superficially long, so widening the area of diffusion. Thus the tendency to localised vesicular change from filtration through the conjunctiva was reduced to a minimum. It was this change which had been mainly responsible for the late infections reported after trephining. Permanent filtration through this incision was secured in chronic glaucoma if the wound were kept open 24 hours. One method of doing this was to fix a gilded metal rod by sutures so that it lay in the incision though upon the conjunctiva, depressing the latter into the scleral groove. The method had the advantage of never emptying the anterior chamber, and during the operation there was only slight leakage. The operation, therefore, seemed to be one of the safest imaginable. Apart from the danger of late infection being lessened, there was less risk of intra-ocular hæmorrhage, and interference was reduced to the minimum. Ordinarily there was no need to interfere with the iris. The details still required to be fully worked out. It was desirable to avoid all unnecessary displacement of conjunctiva, which tended to localise filtration, and in the second place it was necessary to provide sufficiently free leakage of aqueous in congestive and absolute glaucomas.

Mr. N. BISHOP HARMAN submitted a paper on a Variable Flap Operation for Chronic Glaucoma. He devised the operation so as to allow the surgeon some latitude in the grading of the effects intended to be produced. Most of the methods now used were very rigid; the same was done for every kind of eye and every texture of sclera, whether thin or soft, or tough and gristly. After initial scleral section with the keratome the author's modified twin scissors were used to cut a corneo-scleral flap. The blades of the scissors had been so modified that they cut a U-shaped piece free, except for a narrow stalk of attachment to the cornea. This flap was freely movable; the ordinary tension of the eye lifted it above the general level of the sclera. It was so mobile that it could be twisted over on itself; then it was found to lift the conjunctiva and form a sort of inclusion tissue keeping open the scleral fistula. If the sclera were unusually tough the flap could be removed with the touch of the knife. He favoured the operation as securing the desired variation, and the twisting of the flap in particular promised to be very effective.

Mr. W. G. LAWS read a paper entitled "Herbert's Small-flap Operation for Glaucoma." He was inclined to return to the original type of the operation and make lateral cuts with the knife, for scissors must crush and injure the tissues before dividing them; and in glaucomatous eyes the tissue was already of lowered vitality. For that reason he did not apply antiseptics to the conjunctival sac, nor even douche it before operating; he simply cleansed the edges of the lids with 1 in 3000 perchloride. Out of 140 cases he had had intra-ocular hæmorrhage in only three at the time of the operation, and these he described. He did not believe in one form of operation for all glaucoma cases, particularly where the anterior chamber was shallow.

Mr. A. L. WHITEHEAD (Leeds), in discussing the papers, pointed out that after the glaucoma operation fistulous tracts were set up from the anterior chamber towards the spaces of Fontana, lined with epithelium which was probably derived from the anterior chamber. When the operation failed it seemed to be due to the occurrence of a new fibrous tissue formation, which closed the operation wound whatever the operator did. He narrated some cases bearing out his contention.

SECTION OF PATHOLOGY.

Cell Division.—Pseudo-tuberculosis Hyalina Testis.

A MEETING of this section was held on May 5th, Dr. F. W. ANDREWES, the President, being in the chair.

Mr. H. C. ROSS gave a lantern demonstration to illustrate the similarity between certain types of cell division artificially produced by auxetics and certain figures found in the blood in pernicious anæmia. This was in support of his previous work on division of lymphocytes.—An animated discussion followed in which Sir RONALD ROSS, Dr. J. A. MURRAY, Dr. E. F. BASHFORD, Dr. J. W. CROPPER, and Mr. S. G. SHATTOCK took part.

Dr. MURRAY and Dr. BASHFORD then gave a kinematograph display illustrative of the mitotic division of cells in the blood of the newt, in order to show that the phases previously demonstrated by staining methods in fixed films were reproductions of the actual process.

Mr. SHATTOCK, under the name Pseudo-tuberculosis Hyalina Testis, described a condition simulating a nodular tuberculosis of the body of the testis. The term "pseudo-tuberculosis" had rightly been discarded in the nomenclature of infective processes; they no longer spoke, e.g., of a streptotricial pseudo-tuberculosis. The lesions were named after the bacteria or animal parasites causing them. Nevertheless for non-infective lesions the term might still be convenient. Many forms of nodular fibrosis of the lung from dust inhalation were striking simulants of tuberculous disease. In the present case so close was the likeness that the testicle would have certainly been condemned if split through for inspection at an operation prior to a contemplated epididymectomy. The lesion was due to the hyaline degeneration and swelling of the intertubular stroma around groups of seminiferous tubules, of which the cells were similarly thickened and which were in different stages of obsolescence. In the extreme stage the tubuli were represented by thick-walled hyaline cylinders, with the narrowest chink to represent a lumen, the whole of the epithelium having disappeared. As a final change the lumen itself became obliterated. The nature of these structures was determinable by finding epithelium and spermatozoa in their lumen in the earlier steps of the change. Groups of similarly thickened tubuli occurred in this specimen without any accompanying hyaline swelling of the pertaining stroma. Mr. Shattock, on examining the testicles of the aged, had found similar groups of obsolete thickened tubuli, which might be so extensive as to produce macroscopic foci and irregular tracks simulating a tuberculous lesion, without any corresponding involvement of the stroma. The thickening possibly resulted from the local action of the effete products of disintegrating epithelium, and, having a toxic origin, was allied in kind to the hyaline and amyloid thickening of the capillaries in more general disease. In syphilitic and in leprous orchitis tubuli showing the same change might be encountered, whilst the thickening of the walls of the tubuli in the hypoplasic undescended organ had long been pointed out. Such hypoplasic testicles probably functioned for a brief period, their early obsolescence being followed by disintegration of the tubular epithelium, and as a further result by thickening of the walls of the tubes.

MEDICAL SOCIETY OF LONDON.

Ascites and its Treatment.

A MEETING of this society was held on May 11th, Sir DAVID FERRIER, the President, being in the chair.

Dr. DE HAVILLAND HALL opened a discussion on a case of Ascites and its Treatment. The patient was a lady, aged 34, who married at the age of 22, but had had no family. She was seen in September, 1908, and stated that 11 years previously she had had a severe illness with elevated temperature lasting six weeks. Five years later she had influenza with swelling of the abdomen and enlargement of the liver. She was ill for five or six months and had attacks of faintness. She made a good recovery and continued well until the autumn of 1907, when she over-exerted herself while riding—as a result she suffered from dyspnœa. In March, 1908, some cyanosis was noticed, and she was kept in bed for five weeks. After this she had various courses of treatment, including one at Nauheim. When first seen by Dr. de Havilland Hall the patient had a pulse of 108 per minute, it was irregular, intermittent, and small in volume. The area of cardiac dulness was increased, the impulse was outside the mid-clavicular line, there was no thrill and no distinct murmur could be detected. Nothing abnormal was found in the lungs. There was no œdema of the ankles. The liver was enlarged and there was free fluid in the peritoneal cavity. The urine contained neither albumin nor sugar. The diagnosis recorded at the time was "dilatation of the heart with enlargement of the liver, not due to cirrhosis." During the course of the patient's illness she was seen in consultation by Dr. Hale White, Sir R. Douglas Powell, and Sir William Osler. Dr. Hale White considered that the ascites was caused by disease of the liver. Sir R. Douglas Powell expressed the opinion that the condition of the heart was chiefly responsible for the ascites and other symptoms. Sir William Osler only saw the patient later in her illness, when a definite diagnosis was out of the question. In spite of medicinal treatment the ascites increased, so the patient was tapped with Southey's tube in April and June, 1909. The following July Mr. W. G. Spencer performed omentopexy. Six weeks later paracentesis was again required. In April, 1910, femoral drainage was carried out. In June of the same year the abdomen was opened, the lower pole of the spleen was scarified through its capsule, an area of parietal peritoneum the size of the palm was dissected off, and the left kidney decapsulated. The peritoneal cavity was wiped out and a drainage-tube was left in. In January, 1911, doubled strands of large-sized floss silk were passed, after Mr. Sampson Handley's method. One end was left in the peritoneal cavity and the other was brought out through a button-hole over the lower ribs to the posterior fold of the axilla, and a second strand was passed under the right breast. After the last operation the patient gave up all hope of recovery, and though at times she consented to take some drugs she would not continue any definite line of treatment. On several occasions when the output of urine had fallen below a pint in the 20 hours, and once to 12 ounces, the administration of tabloids of pituitary extract had the effect of increasing the amount of urine to nearly 4 pints in the 24 hours. Unfortunately the good effect soon passed off. The repeated tappings, 49 in all, gradually weakened the patient, she got œdema of the lungs and ankles, and in May, 1913, after a cheerful "Good night" to her family, she took 240 grains of medonal and died comatose 48 hours later. The post-mortem examination was made by Dr. B. H. Spilsbury. The pericardium was completely obliterated by old adhesions; over the apex and the posterior surface of the heart there was extensive calcification, forming an almost complete carapace for that part of the heart. The heart was apparently not enlarged. Slight thickening of the free edges of the mitral cusps was present. The myocardium showed advanced fatty degeneration. The peritoneum was thickened, especially over the liver and spleen. Firm adhesions were found over the liver and spleen and between the coils of the small intestine. The liver weighed 72 ounces and showed everywhere most advanced passive congestion, as did also the spleen and kidneys. Dr. Spilsbury regarded all the changes as the result of the pericardial disease. Dr. de Havilland Hall pointed out the difficulty of the diagnosis in the case under consideration. Sir R. Douglas Powell was in favour of the cardiac origin of the trouble, whereas Dr. Hale White regarded the liver as the primary seat of the mischief. The question of pericardial adhesion was not definitely raised by any of the physicians who saw the patient, but in the light of the post-mortem examination the history of the case emerged fairly clearly. It was impossible to give a correct diagnosis to the first illness from which the patient suffered, but the illness which occurred five years later was more probably rheumatic than influenzal, and the commencement of the pericarditis might be assigned to this time. Dr. de Havilland Hall laid it down as an axiom that in the presence of the signs of cardiac failure and the absence of any valvular lesion the existence of mural degeneration or pericardial adhesions must be postulated to explain the symptoms, and these two conditions often coincided, as in the case under consideration. The case emphasised the fact that the symptoms of adherent pericardium might be almost entirely of hepatic origin and might give rise to the erroneous diagnosis of cirrhosis of the liver—i.e., Pick's *pseudo-cirrhosis* syndrome. After discussing the medicinal treatment of ascites, Dr. Hall described the various operative methods which have been employed for the relief of chronic ascites. (1) Omentopexy—the Drummond-Morison or Talma operation; (2) Dr. Essex Wynter's plan of femoral drainage; (3) the formation of adhesions between the spleen and the abdominal wall and decapsulation of the kidney; (4) drainage by means of strands of silk passing from the peritoneal cavity into the subcutaneous tissue of the thorax; (5) the formation of a communication between the internal saphenous vein and the peritoneum; (6) the direct union of the internal saphena vein to one of the branches of the portal vein; (7) an operation recently devised by Rosenstein with the object of providing a permanent drain from the peritoneal cavity into the bladder; and (8) a method called the auto-serum treatment had been advocated. After having punctured the peritoneal cavity and drawn some of the ascitic fluid into the syringe the needle was withdrawn only so far as to leave the point just under the skin. The fluid was then injected into the subcutaneous tissue. The dose to start with was 3 c.c. and the amount should be gradually increased. The injections should be given about once a week, and 10 or 12 might be needed. They were said to cause a great increase in the output of urine. Dr. de Havilland Hall recommended paracentesis by means of Southey's tube, so as to allow of the gradual emptying of the peritoneal cavity and the avoidance thereby of shock.

Sir R. DOUGLAS POWELL said that Dr. de Havilland Hall deserved the thanks of the society for bringing forward a case of great value and importance in so complete a manner. It would afford an opportunity of discussing many interesting methods of treatment of abdominal dropsy and the importance of a correct diagnosis as a guide in differentiating cases to which each method might be expected to be most applicable. The case was interesting and important, too, in exemplifying in a striking manner how much treatment of disease had been advanced by the Listerian methods. He remembered well after his student days how impossible it was even to open an abdomen or a joint, much less to scrape, detach, transplant, or anastomose any portion of their walls. Each of the many methods of treatment adopted in this case gave relief (1) from direct pressure in abdomen and (2) by lightening the load of the heart through serous depletion (which had become checked by intra-abdominal pressure).

For those purposes the abdominal tappings and laparotomy were probably most efficacious. But the continued loss of serum proved in time very exhausting and could not long be endured by persons of broken constitution. Mr. Handley's and Dr. Wynter's methods were less exhausting by keeping the serum in the organism, and whilst affording mechanical relief to the local impediment at the same time relieved the general circulation by stimulating kidney secretion. The auto-serum treatment seemed also in some degree to act as a diuretic. It was to be observed, however, that the mechanism of defect in the circulation in this case was of a kind quite different from that which obtained in cases of cirrhosis in which anastomotic diversion of blood current was often of great value. He had, for instance, seen a case of uræmic convulsions completely relieved by Edebohl's operation of stripping the renal capsules, but here, as in cirrhosis, the difficulty was one of local obstruction of vessels. In the present case the difficulty was of central source in a failure of heart power from intrinsic disease of that organ. The *vis a tergo* of the circulation was impaired and was not sufficient to propel the blood through the great venous channels. The great portal and other abdominal sections of the venous reservoir—or, as it was picturesquely termed by Professor Keith, the venous cistern—became stagnant, and the aspiratory aids to the circulation or *vis a fronte* were insufficient to compensate for the defect. Hence abdominal stagnation and serous effusion. It was still a mystery why in some cases of heart failure abdominal dropsy either alone or out of all proportion to general œdema occurred, and in others (the majority) the reverse. In the presence of such central failure so much benefit could not be expected from anastomoses effected by omentopexy or adhesions as would arise in cases where the difficulty was due to obstruction in the capillary terminals of the portal vessels. By retaining more blood in the arterial system, and by stimulating such muscular substance as could respond in the heart, such remedies as digitalis and pituitary extract were of temporary use in increasing the kidney function.

Dr. W. **HALE WHITE** spoke of the possible value of pituitary extract as a diuretic. From physiological researches one would expect it to increase the output of urine, but he had found that it did so only temporarily. Copaiba had often proved an excellent diuretic for people with ascites. Collections of fluid connected with diseases of the heart might occur in one locality only, and this fact illustrated how little we knew as to the cause of œdema in heart disease. For the sake of argument he would dissent from the view that the case was primarily one of heart disease. There was a considerable degree of cirrhosis and the liver had been noticed to be large and nodular. He thought it would be agreed that passive congestion from heart failure did not give rise to a degree of cirrhosis which was obvious at an operation or post mortem. We had little knowledge of the cause of cirrhosis. Alcohol could only be considered as a contributory cause. It was much commoner in London than in either Glasgow or Aberdeen, where spirit drinking was certainly not less. Mahomedans had been shown to be affected by it. In the cases described by Dr. S. A. K. Wilson under the title "progressive lenticular degeneration" a gross form of cirrhosis of the liver was an important feature. It also occurred in children when there was no suggestion of alcohol drinking. There was, therefore, some cause for cirrhosis at present unknown. He questioned whether an ascites which frequently recurred was found apart from a morbid condition of the peritoneum. In polyserositis the peritoneum usually bore the brunt of the disorder, and in that condition the abdomen might be tapped an enormous number of times. Kelly had, however, described a variety in which the pericardium was chiefly affected. He would suggest that the nature of the case which formed the basis for the discussion was polyserositis and cirrhosis, though possibly he had exaggerated the importance of the cirrhosis.

Mr. **WALTER G. SPENCER** said that he regarded the Talma-Morison operation as a physiological anastomosis. The difficulties in the operation devised by Dr. Essex Wynter were that fluid leaked into the legs and prevented the patient from getting about, and there was the mechanical difficulty of keeping the tube from becoming blocked. The same applied to Mr. Sampson Handley's method. He had found that the silk strands used became permeated with young fibrous tissue. The value of the Talma-Morison operation was further enhanced by the opportunity it gave of exploring the abdomen, for by that means gummata might be discovered or papilliferous ovarian cysts. Exploration by laparotomy might throw an important light on such cases.

Dr. H. **MORLEY FLETCHER** said that the diagnosis was not perfectly clear even now, although that of polyserositis was highly probable. It was still uncertain whether it was usual to find a great amount of cirrhosis of the liver in such cases. He did not think that the heart was primarily at fault. What was the cause of the mediastino-pericarditis found? It was generally believed to be tuberculous, but might possibly be due to some other infection. The degree of cirrhosis was in advance of what one would expect to find.

Dr. B. H. **SPILSBURY** said that the post-mortem appearances were very unusual. The liver weighed 70 ounces and was in a very advanced state of cirrhosis. The capsule was greatly thickened. The cirrhosis was not uniformly distributed, but rather was suggestive of a late syphilitic cirrhosis. The fact that the cirrhosis was more pronounced on the superficial part of the organ suggested that it was due to nutmeg congestion. A careful examination of the deeper parts of the liver revealed congestion of the intralobular veins and fresh fibrosis taking place side by side. He concluded that it was an extremely rare form of replacement fibrosis, secondary to congestion. Possibly it was the remittance of the congestion which accounted for the unusual degree of replacement fibrosis in such cases. He had seen only five similar ones out of some hundreds of examples of ordinary nutmeg congestion.

Dr. **DE HAVILLAND HALL** briefly replied.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Address on Insanity.

THE spring meeting of the South-Eastern division of this association was held on April 30th at Chiswick House, Chiswick, Dr. **JAMES CHAMBERS**, the President, being in the chair. The election took place of representatives on the general council of the association for 1914–15.

Dr. T. **SEYMOUR TUKE** read a communication giving interesting records of work done at Chiswick House since the transfer in 1893 of the licence (granted in 1845 to the late Dr. Harrington Tuke) from the Manor House, Chiswick. In a retrospect of these 21 years he expressed the view that the results of much extended knowledge of insanity and its pathology had not been as great as one might have expected. This was decidedly disappointing. Some 70 years ago and more his distinguished grandfather, Dr. Conolly, succeeded, with the help of other physicians, in convincing thoughtful people that insanity was a physical disease. The advantage to the community at large, and especially to the insane, of this education of the public could not be over-estimated. Then came a period of eagerness on the part of scientists to attain a more accurate knowledge of the pathology of insanity. As a result there were a constantly increasing number of post-mortem and laboratory observations. But the question now suggested itself, How much have these scientific investigations helped the practical physician who undertakes the treatment of the disease? Is the percentage of permanent cures of insanity in the United Kingdom as much higher now than it was 30 years ago as might be expected after so great an amount of research? Dr. Tuke enumerated some of the reasons why in his opinion successful treatment had not made a greater advance. Foremost among these he put the increasing selfishness of the age and the greater frequency with which the word "uncertifiable" was used in regard to cases which had really passed the "border-line," also the increasing dilatoriness on the part of general practitioners about signing certificates, even in cases in which there ought to be no hesitation. With regard to the latter, he was inclined to fear that much valuable time was often lost while waiting for the results of laboratory investigations. Such adjuncts to the means of diagnosis had an undoubted value; but while they were being collated days were passing in many cases during which therapeutic measures for the benefit of the patient might have been adopted that ought never to be delayed. Among these he specially referred to removal from unfavourable surroundings, and said that no drugs could ever supersede good air, wisely regulated exercise, freedom from unnecessary control (however well intentioned), and nursing by those accustomed to deal with the insane. He feared there was too much dependence at the present time on the hypodermic introduction of drugs and other forms of chemical restraint.

A short discussion followed, in which Sir GEORGE SAVAGE, Mr. JAMES STEWART, Mr. J. NOEL SERGEANT, and others took part.

A vote of thanks to Dr. Tuke terminated the proceedings.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—The last meeting of the session was held at the Leeds Infirmary on May 1st, Dr. T. Wardrop Griffith, the President, being in the chair.—Dr. R. G. M. Ladell read a paper entitled "Some Practical Points in Connexion with the Use of Therapeutic Suggestion." He said that therapeutic suggestion could be practised without actual hypnosis. Even where hypnosis was aimed at in nine out of ten cases the patient did not actually sleep, and it was a great mistake to let the patient think that sleep was a necessary preliminary to cure. Hysterical subjects were not good cases as they were already under the influence of their auto-suggestion. Neurotic cases, drug takers, and alcoholics were suitable cases for treatment. Neurasthenics required other treatment as well, but therapeutic suggestion was of great assistance. It was important that the patient should understand that the treatment differed widely from the popular idea of hypnotism as set forth in novels and plays. It strengthened the will power instead of sapping it, and the subject remained his own master all through. Suggestions must be adapted to the patient. With some patients one could be dogmatic; others required reasoned arguments. The effect was cumulative and could not be judged by a single sitting. Nothing should be done to any patient which was not done with the object of facilitating his cure. Experiments should only be performed on healthy subjects.—Dr. M. J. Stewart showed a series of microscopic preparations illustrating some of the conditions under which local deposits of cholesterin occur in the tissues, with remarks on the cellular reactions induced. The specimens shown included chronic mastitis, with rosette-like groups of giant cells arranged round bunches of the crystals; squamous epitheliomata with advanced cornification; teratomata of the testis; subacute cholecystitis; adeno-carcinoma ovarii papillare; fibro-xantho-sarcoma; and thyroid cyst. The most striking feature of the cellular reactions induced was the constant occurrence of large numbers of giant cells of the foreign-body type whenever the crystals were deposited in the midst of living vascular tissue.—Dr. G. W. Watson showed a case of Ulcerative Colitis which had made a striking improvement under treatment. The patient was a man, aged 40, who had been troubled with severe abdominal pain, associated with diarrhœa and the passage of bloody and mucous stools, for over a year. Cæcostomy had been performed in Newcastle with absolutely no benefit. When he came under observation three months ago emaciation was extreme, his weight being only about 7 st. He was treated with sterilised kaolin, and from the first week of administration he began to improve. At the present time he weighs over 12 st. and feels perfectly well.—Cases and specimens were also shown by Professor J. B. Hellier, Dr. W. Gough, Mr. J. A. Coupland, Mr. J. F. Dobson, Dr. R. A. Veale, Dr. T. Churton, Mr. S. W. Daw, Mr. E. R. Flint, Dr. C. W. Vining, and Dr. A. H. Miller.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on April 23rd, Dr. E. W. Hope, the President, being in the chair.—Dr. K. Grossmann, Dr. R. Stopford Taylor, and Dr. R. W. McKenna showed a case of Epithelioma of Eyelid Treated by Radium. The tumour grew painlessly for 12 months. Radium was applied for 500 hours in all, at first for seven hours daily, and then for four hours daily, with the result that the tumour disappeared and the condition of the eye became almost normal. The pre-auricular gland, which was enlarged when treatment was undertaken, gradually diminished.—Dr. John Campbell read a note on Five Cases of Osteitis Deformans. The father and four children were affected. No history of syphilis could be obtained, and there was no evidence of the same. The father, who was shown, presented the characteristic attitude and deformities. The pain was not severe; diarrhœa, weakness, and emaciation were progressive features. Palpitation and dyspnœa distressed him. There were no blood changes, and the Wassermann reaction was negative.—The President, Mr. G. P. Newbolt, Mr. K. Montsarrat, and Mr. R. W. Murray discussed the note; Dr. Campbell replied.—Dr. J. Murray Bligh read a paper on Infant Feeding. He began by giving a comprehensive review of the art of infant feeding in Roman, Tudor, Elizabethan, Stuart, and Victorian times. He showed that from the middle of the sixteenth century to the middle of the nineteenth century the professional wet nurse was the only alternative to maternal suckling. The advent of the bottle and artificial foods dated from the beginning of the nineteenth century. In his opinion the bottle was an invention of which Herod himself might be proud, and he held the view that the effect of artificial feeding on family life was only comparable with that of poverty and syphilis. Underwood's work was referred to as creating another epoch. Dr. Bligh deplored the waste of energy shown by brilliant investigators who devoted their time solely to the preparation of artificial foods and the sterilisation of milk rather than to the much more important problem of the increasing lack of power possessed by the woman of to-day to suckle her own infant. In his opinion the modern mother was censurable and abysmally ignorant. He concluded with the remark that the vocation of woman was the adequate fulfilment of her destiny.—The President drew attention to the fact that the infant of to-day was cared for on all sides and in all ways to a remarkable extent. He emphasised the value of the Notification of Births Act in dealing with the infants, and stated that it was the duty of all sanitarians to get the mother to do her duty.—Professor J. M. Beattie pointed out that the electric sterilisation of milk was to prevent certain diseases due to the consumption of unsterilised milk, and said that no one was a more ardent believer in maternal suckling than himself.—Dr. F. H. Barendt spoke as a family man, and referred to the old saying, "nine months in and nine months out."—Dr. N. P. Marsh regretted that the wet nurse had fallen into disrepute. In their order of merit he placed sterilisation of milk first and scalding of milk second. He upheld the value of percentage feeding, and regretted the costliness of this method. —Dr. Bligh replied.

A CORNISH CENTENARIAN.—Mrs. Hannah Bailey died at Falmouth on May 1st, aged 101 years. The deceased was born on August 7th, 1812.

CARAVAN CLUB.—The annual dinner of the Caravan Club of Great Britain and Ireland took place at the Café Monico on May 6th, the chair being taken by Major Alfred C. Tunstall, R.A.M.C. (T. retired). The secretary, Mr. Harris Stone, in proposing the toast of "The Road," referred to the accidental coincidence that May 6th was April 23rd (O.S.), St. George's Day, so that while they were feasting in London there were thousands of gipsies feasting in Eastern Europe, celebrating the arrival of spring and the resumption of nomad life after a comfortless winter within the walls of a house, who would invite every passer by to join in their feasting and festivities. Dr. T. N. Kelynack, in responding, dwelt upon the hygienic and economic advantages of the open-air life, which was on all fours with modern ideas as to the superiority of prevention over cure of disease, and he said that all in delicate health would do well to join the ranks of the caravanners, while incidentally they would escape part of the increasing burden of rates and taxes. He mentioned also the great public services which were rendered by Lady Aberdeen's caravans in Ireland and by those of the Women's Imperial Health Association. "The Caravan Club" was proposed by Mr. Wilfred Mark Webb and responded to by the Chairman. Commander Charles Eldred, R.N., proposed the toast of "The Visitors," which was responded to by Dr. Albert Wilson, who said that at present the nation was going to pieces "on its nerves," and he suggested caravanning as a remedy. In responding to the toast of his health Mr. Stone spoke of the services that the Caravan Club could render to the country in case of war, for he personally knew of an enormous amount of equipment which could be placed at the disposition of the army and the medical department.

Reviews and Notices of Books.

Defensive Ferments of the Animal Organism against Substances out of Harmony with the Body, the Blood Plasma, and the Cells; their Demonstration and their Diagnostic Significance for Testing the Functions of Different Organs.

By EMIL ABDERHALDEN, Director of the Physiological Institute of the University at Halle a.S. Third enlarged edition. With 11 text figures and 1 plate. English translation by J. GAVRONSKY, M.R.C.S. Eng., L.R.C.P. Lond., M.D. Halle; and W. F. LANCHESTER, M.A. London: John Bale, Sons, and Danielsson, Limited. 1914. Pp. 242. Price 7*s.* 6*d.* net.

IN our review of the second German edition of this work[1] we expressed the wish that the second edition might have as rapid a success as its predecessor. Our wish has been more than fulfilled. Now we have an English translation of the third German edition. It took less than three months to exhaust the second German edition—an indication that this new field of research has excited much interest. At the outset we desire to compliment the translators on the manner in which they have rendered into English the German text. For the words "fremd" and "eigen," as they are used in the original, it is difficult to find an exact equivalent, but we think the terms "harmony" and "disharmony" used by the translators fairly meet the conception of the author. We have only one suggestion to make: we could have wished that the text had been arranged in chapters, more especially as there is no index. On comparing this edition with the second German edition we find a few additions here and there. In the "Contents" three items have been added, but otherwise the text is much the same. There is a not inconsiderable addition to the bibliography. A review of the first edition will be found in THE LANCET of Jan. 4th, 1913, p. 39. The word "albumen" is sometimes used where "protein" might be preferable, and we are introduced to a new word, "decomposites," for "spaltproducten."

We have already dealt so fully with the two German editions that it now only remains to emphasise a few points. Having regard to the fact that blood plasma is unable, either in the majority of animals or in man, to produce decomposition of albumins, peptones, and polypeptones, or fats, and only in some instances of carbohydrates, the question arises whether the blood plasma exhibits new properties in cases in which substances are introduced, and which are out of harmony with the plasma and particularly with the body. The author's experiments prove conclusively that by introducing substances which are out of harmony with the species and with the plasma, the body defends itself by the production of specific "ferments" that are directed against special kinds of substrates. The ferments in the plasma persist for a long time after the introduction of disharmonious substances, whether they be products of proteins or of carbohydrates. The lymph is regarded as a "buffer"—a "neutral" zone—between the cells of the blood and those of the body. The application of these phenomena to the diagnosis of pregnancy—serodiagnosis—is now acknowledged. The animal organism, within certain limits, generally defends itself by means of ferments—e.g., proteolytic, pepsin, trypsin, erepsin—against compounds that are capable of decomposition and that consist of many elements. The application of these discoveries to pathology, to clinical medicine, and to the functions of organs is illustrated with regard to carcinoma, nephritis, and other diseases.

We feel sure that this translation will be welcomed by all who take an interest in a new biological problem of commanding scientific and practical interest.

International Clinics.

Twenty-third Series, 1913. Vols. I., II., III., and IV. London and Philadelphia: J. B. Lippincott Company. Vol. I., pp. 302; Vol. II., pp. 312; Vol. III., pp. 303; Vol. IV., pp. 312. Price 35*s.* net the four volumes.

VOL. I. of this series includes diagnosis and treatment, medicine, pædiatrics, surgery, obstetrics, electrotherapeutics, and a review of the progress of medicine during the year 1912. The volume opens with a well-written paper by Dr. George E. Malsbory on the treatment of poliomyelitis, including an opening section on the prevention of the spread of the disease, the question of the possibility of stomoxys calcitrans as an infective agent being considered. Stress is laid upon the necessity for keeping the upper respiratory tract clean, and if the temperature should rise high a hot bath gives much relief. Dr. Francis Reder provides an interesting note upon a sign of diagnostic value in obscure cases of chronic appendicitis. This sign is elicited by rectal palpation. If the finger be passed for some 3½ or 4 inches above the anus an aggregation of circular fibres known as O'Beirne's valve will be felt. When the finger has reached and recognised this and any pain felt by the patient owing to the presence of the finger has subsided, the finger is "gently pushed upward toward the right iliac fossa, when, in the event of an appendix lesion, the finger will touch a point beyond the valve that will cause great pain." Dr. Reder has verified the accuracy of the diagnostic worth of this sign in some 200 cases. We must, however, confess some scepticism as to the trustworthiness of this sign, and we consider a surgeon would be unwise who would decline to operate in the absence of it. A practical and useful paper is contributed by Dr. I. D. Steinhardt on the diagnosis and treatment of scarlet fever. Dr. Albert Abrams discusses the treatment of aneurysms by concussion of the seventh cervical spine, a method which he claims causes contraction of the dilated vessel. In other papers in Vols. II., III., and IV. he refers to this method as an aid to diagnosis, as a means of procuring cardiac contraction, and by a variant of the method—namely, percussion between the third and fourth dorsal spines—he claims to bring about a diminution in blood pressure. In the section on medicine Dr. James Walsh, so well known for his studies in mediæval medicine, reprints an amusing lecture on disease simulation which he delivered at the Fordham University School of Medicine. In the surgical section the most interesting paper is by Dr. J. Torrance Rugh, giving an account of Albee's method of bone-grafting in Pott's disease, with a report of ten cases in which Dr. Rugh performed the operation successfully. He recommends a longer period of support by braces of plaster-of-Paris—namely, eight months or more—after operation than did Albee, who allowed his patients to go without support in from three to six months, but this need for prolonged support with plaster-of-Paris must raise a doubt as to the efficacy of the bone grafts.

---

[1] THE LANCET, Nov. 8th, 1913, p. 1325.

Vol. II. commences with two papers dealing with allied subjects by Dr. G. M. Illman and Dr. H. B. Hemenway respectively. The first is a simple account of the therapeutic indications for antitoxins, serums, and vaccines, while the second, entitled, "Principles of Therapy under Modern Biology," deals with, besides bacterial products, such remedies as atoxyl, lactic acid and its ferment, and the use of citric acid for promoting the fluidity of the blood. Dr. H. W. Frauenthal in a very practical paper gives an account of a system of treating infantile paralysis, lateral spinal curvature, and locomotor ataxy by exercises performed before a mirror, so that the patient can see what he is doing and concentrate his mind on exercising the necessary muscles to overcome the deformity or develop coördination. In infantile paralysis electricity is also used. Dr. A. Rose writes on the continuous warm water bath in tuberculosis and infectious diseases in general. Dr. Rose, who prefers to call tuberculosis by its Greek name of phymatiasis, draws attention to the well-known beneficial effects of the continuous bath in cases of chronic sepsis, such as may follow extensive burns. It benefits by removing septic products and by stimulating metabolism. He claims that it is also of great use in cases of tuberculosis, whether pulmonary or in the bones or joints. Dr. C. H. Browning and Dr. H. F. Watson, writing on paroxysmal hæmoglobinuria, quote six cases under their own care and sundry cases from the practice of others which, in their own words, "constitute a very strong basis for the opinion that syphilitic infection is practically invariably present in cases of paroxysmal hæmoglobinuria *a frigore*." In the section of surgery Dr. P. G. Skillern, jun., of the Philadelphia Hospital, publishes a most interesting account of a year's fracture work at the surgical dispensary of the University (Pennsylvania) Hospital. There were 299 cases of fracture treated during the year 1912, including six cases of fracture of the tarsal bones and three of fracture of the metatarsals. Of the tarsal cases three were of the os calcis, two of the astragalus, and one of the cuboid. In the obstetrical section Dr. J. Wesley Bovee gives his experience of the use of iodine in abdominal surgery. He uses a 3½ per cent. solution in 95 per cent. alcohol, and as a preliminary to opening the abdomen and peritoneal cavity for the treatment of affections of the pelvic structures he injects an ounce of this solution into the uterus. Sometimes the fluid escapes into the peritoneal cavity, but no harm is said to result. In the medico-legal section Dr. Gurney Williams, sometime district police surgeon of Philadelphia, publishes the first part of a paper upon rape in children and young girls. The second part appears in Vol. III., and the whole paper is full of practical points which will be useful to those practitioners who are brought into contact with this class of case.

Vol. III. leads off with two papers dealing with tropical medicine. The first, by Dr. C. F. Craig, of the United States Army Medical Corps, is a simply written account of the prophylaxis and treatment of malarial affections. In the second paper Dr. Baily K. Ashford, also of the United States Army Medical Corps, writes on uncinariasis founded on an experience of the disease at Porto Rico. The clinical features of the complaint alone are discussed. The drug found to give the best results was thymol, but in some cases where this was not well borne beta naphthol was substituted. Dr. Norman B. Gwyn writes upon the treatment of pneumonia as seen at the Philadelphia Hospital during the winter of 1912–13. The paper would have been of greater value if the varying treatments and results had been more clearly tabulated. The section on medicine is devoted to two papers by British surgeons—Mr. Peter Daniel and Mr. E. M. Corner—upon Gastro-intestinal Toxæmia. Mr. Daniel attacks Sir Arbuthnot Lane's views on intestinal stasis, while Mr. Corner recommends careful dieting, purgation, and the surgical removal of obstructions if there be any.

In Vol. IV. we note a paper by Dr. A. B. Hirsh, of Philadelphia, on Newer Methods in the Treatment of Neuritis, of which the chief are radiant light and heat combined with the static wave. Another interesting paper, dealing with static electrical treatment, is contributed by Dr. W. B. Snow, of New York. In the section on medicine Dr. F. Proescher writes upon filterable viruses, such as rabies, poliomyelitis, and variola, and the staining of micro-organisms found in them, which may or may not be the causative organism, by means of the thiazine group of dyes. In the neurological section Dr. Walsh has again an amusing paper upon neurotic discomfort and the law of avalanche, in which he lays stress upon the well-known but little appreciated fact that directly the composition of a quack remedy becomes known its popularity disappears.

Spezielle Pathologie und Therapie innerer Krankheiten.

Edited by FRIEDRICH KRAUS and THEODOR BRUGSCH. Lieferungen 17–24. Berlin: Urban und Schwarzenberg. 1913. Pp. 261–714. Price 2 marks each Lieferung.

THIS excellent text-book on special pathology and therapeutics of internal diseases continues to appear in parts at short intervals. The present instalment maintains the high standard already set. The articles contained in it embrace chapters on Varicella, Variola, and Vaccination, by Dr. E. Mairinger, of Vienna; on Epidemic Parotitis, by Professor J. Citron, of Berlin; and on Measles, German Measles, and Scarlet Fever, by Professor Bruno Salge, of Strasburg. Dr. H. Hetsch, of Hanover, deals with Anthrax. There are a good many illustrations, several in colour and of considerable excellence. We note that Professor Salge does not think that the existence of a "fourth disease," apart from mild scarlet fever and rötheln, is established. He points out also that the endocarditis which may accompany articular complications in scarlet fever is usually benign, but that it seems to have the effect of rendering any subsequent rheumatic valvular affection more severe. In regard to anthrax Dr. Hetsch expresses no definite opinion as to the advisability of operative interference in cutaneous cases, surgeons still holding contradictory views.

Dr. Hetsch also treats of glanders in both man and animals. He summarises the methods of diagnosis in order of importance, and he also is responsible for the articles on Foot and Mouth Disease and on Hydrophobia; in this latter is a coloured plate showing Negri's bodies. Dr. Plaut describes the Mycoses under the headings of moulds, blastomycetes, thrush, sporotrichoses, and streptotrichoses. This section is especially well treated. We cannot at the moment think of any work in which existing knowledge of this comparatively new subject is so ably summarised, both from a pathological and clinical aspect. The final section deals with Poliomyelitis, by Dr. Paul Römer. To each section is appended an extensive bibliography.

Although we have laid special stress on the section dealing with the diseases associated with fungi, we should add that the other sections are of the same standard. There are numerous illustrations, including coloured plates of the various diseases, drawings of fungi and coloured representations of cultures, which add to the value of the work as a whole.

Therapeutics of the Circulation.

By Sir LAUDER BRUNTON. Second edition. With 111 illustrations. London: John Murray. 1914. Pp. xxiv. + 536. Price 5s. net.

THE second edition of Sir Lauder Brunton's book on the therapeutics of diseases of the heart and blood-vessels contains a large amount of information, and illuminates many points in the physiology and pathology of heart disease that are not usually discussed in books dealing with this subject. Compared with the first edition, which was founded on eight lectures delivered in 1905, it shows evidence of rearrangement and much rewriting.

It contains 19 chapters, of which the first six deal, broadly speaking, with the physiology of the heart and circulation. Then follow nine chapters on the pathology and pharmacology of the diseases of the blood-vessels and heart. The last four chapters are devoted to treatment. There is an index most lavishly conceived and executed, and in addition an index of the authors quoted. The volume abounds in references to the literature, and gives a clear picture of modern views of cardio-vascular disease as they present themselves to a highly skilled and scientific clinician.

There can be few British medical men who are unacquainted with the author's *lucid* style and practical method of exposition. In this book they will find a sound and up-to-date account of the subject dealt with, and full descriptions of the various therapeutic measures employed in the relief of the symptoms of cardio-vascular disease. It may be cordially recommended to students and practitioners of medicine.

Handbuch der Vergleichenden Physiologie.

Herausgegeben von HANS WINTERSTEIN. 41. Lieferung. Band III. Physiologie des Energiewechsels. Zweite Hälfte. Seiten 947–1089, Titel und Inhalt. Jena: Gustav Fischer. 1914.

THIS part completes the story of the Physiology of Reproduction as set forth by E. Godlewski, of Cracow. It deals with heredity in its various aspects, Mendelism, experimental investigations to explain the observed phenomena, polyspermia, and chromosomes. The remainder of the text is taken up with the literature relating to reproduction, the index (which occupies more than 40 pages), and the list of contents.

MISCELLANEOUS VOLUMES.

OBITUARY notices of two surgeons who died during the past year, one a veteran and the other cut off before his prime, appear in the *St. Bartholomew's Hospital Reports*, Vol. XLIX., 1913. (London: Smith, Elder, and Co. 1914. Pp. 192 + 195. Price 6s. or 8s. 6d.) The sympathetic memoir of Mr. Alfred Willett, from the pen of a colleague whose initials are now as well known at Cambridge as they were at St. Bartholomew's, gives an interesting impression of the internal politics of the Royal College of Surgeons of England. Of Mr. R. B. Etherington-Smith there are two charming memoirs, which deal with different phases of his life; the second, written more particularly from the Cambridge point of view, supplementing the first, which is a touching estimate, by a senior colleague, of the irreparable loss sustained by St. Bartholomew's Hospital through the death of "the youngest and certainly the best-beloved of all our surgeons." The medical and surgical papers in this volume of the Reports are seven in number. Dr. A. F. S. Sladden describes a trial of some tests for pancreatic disease, principally Cammidge's test, Loewi's test, examinations of fæcal fat, and Kashiwado's test; Dr. T. H. G. Shore contributes a note on the blood in myelocytic leukæmia in relation to prognosis; Dr. Hugh Thursfield writes on acholuric jaundice and the operation of splenectomy; Mr. D'Arcy Power contributes a paper, read at Düsseldorf last October, on ulcerative colitis and its treatment by appendicostomy; and Mr. A. L. Moreton describes a case of post-orbital arterio-venous aneurysm successfully treated by ligature of the internal carotid artery by Mr. H. J. Waring. Dr. Garnet W. Twigg describes an investigation into pes cavus as an initial sign of nervous disease, with a short introductory note from Mr. R. C. Elmslie. Lastly, Dr. Haldin D. Davis recounts experiences in the skin department with neosalvarsan since September, 1912, briefly describing cases of special interest. Ninety doses were given during the 12 months under review, without accident or regrettable incident, and from a clinical standpoint the results were considered to be good. The Reports close with a descriptive list of pathological specimens added to the Museum and the customary statistical tables of the in-patients treated during 1912, compiled and analysed by the medical and surgical registrars.

In the *Transactions of the American Climatological Association*, 1913, Vol. XXIX. (Philadelphia: The Association. Pp. 357), to select only a few of the papers, Dr. Henry Sewall discusses the auscultatory determination of early pathological changes in the lungs, in which the importance and manner of distinguishing between intrinsically mural and purely visceral vibrations are respectively urged and described, Dr. G. W. Norris the anatomical causes for the differences in the physical signs over the upper lobes of the lungs, and Dr. Philip King Brown the early lesions of tuberculosis of the lungs; Dr. J. C. Wilson treats of blood spitting in heart disease; Dr. P. M. Carrington considers favourably the relations of the San Diego (California) region to renal diseases; Dr. Guy Hinsdale describes the mineral springs of America in their chemical, physical, and therapeutical characters; Dr. Robert H. Babcock inquires into the cause of bronchial asthma, and summarises our knowledge of the relation between asthma and nasal disease in the light of anaphylaxis; Dr. James M. Anders describes the rôle of physical exercise in the open in the prophylaxis of tuberculosis; Dr. Cleveland Floyd describes the methods, uses, and limitations of artificial pneumothorax in chronic pleuritic and pulmonary infections; and Dr. H. L. Barnes and Dr. F. T. Fulton report 17 far advanced and progressive cases of pulmonary tuberculosis thus treated, in which 12, or 70 per cent., had life prolonged. A year's observations of symptoms in cases of advanced tuberculosis in the Los Angeles County Hospital in connexion with weather conditions are detailed by Dr. C. C. Browning; Dr. W. C. White and Dr. Paul Shuey discuss the influence of smoke on acute and chronic lung infections; Dr. Judson Daland reports some clinical observations on blood pressure; and Dr. Joseph H. Pratt discusses the action of carbonic acid baths on blood pressure in cardiac disease; the effect of climatic changes on rheumatism and neuritis is dealt with by Dr. James Dudley Morgan. There are many other papers dealing with various subjects in internal medicine less intimately connected with climatology. The volume also contains memorials of the late Dr. C. T. Williams, Dr. R. G. Curtin, and Dr. E. L. Shurly.

Dr. CHARLES J. RYAN'S *Health Preservation in West Africa* (London: John Bale, Sons, and Danielsson, Limited. 1914. Pp. 96. Price 5s. net) is devoted mainly to the personal measures necessary for the preservation of health in West Africa, in four different colonies of which land the author has resided, but, as he himself states, much of what he has to say is applicable to tropical countries in general. It is quite true, as the author states in the preface, that some individuals survive, and even thrive, there who are regardless of care; but he very properly insists that this immunity is extremely rare indeed, and to argue that all can do what a few have done is contradicted by experience in every event of life. The book gives in Chapter I. a brief statement of the nature, causation, and characteristics of the principal tropical diseases encountered on the coast. In Chapter II. the necessary personal preventive measures are described. Chapter III. deals with camp sanitation, while Chapter IV. discusses the hygiene of diet, bathing, exercise, and so forth. Sir Ronald Ross, in an introduction, tells us that, while organised sanitary measures have been exceedingly efficacious, no inconsiderable part of the improvement in health that has taken place in recent years in West Africa is due to the work and advice of medical men, such as Dr. Ryan, "who have spared no effort to persuade Europeans there to do their best to protect themselves against the ever-present infections which caused such havoc among their predecessors," and he highly commends the contents of the book. Our survey of the book confirms Sir Ronald Ross's opinion. ——*Lessons in Elementary Tropical Hygiene, for the Use of Pupils in Tropical Schools*, by HENRY STRACHAN, C.M.G., L.R.C.P. Lond., &c. (London: Constable and Co., Limited. 1913. Pp. 116. Price 1*s.* net), treats in the simplest possible language of the most important diseases of hot climates, and instructs the children what they should do to avoid getting ill; there is also some elementary information as to air, water, food, and general sanitation. The pages on disease prevention are written very clearly, and are well adapted to a child's comprehension. They are also illustrated by numerous figures, though these are too small for use by children; probably they are reductions of diagrams. The latter part of the book is so highly compressed as to be difficult of assimilation by the youthful mind; it is probably meant to furnish a groundwork for oral teaching. The percentage composition of foods is hardly to be grasped by young children; and if the figures are given the protein constituents should not be called "nitrogen" (page 92).——In a handy little pocket book, *Indian Home Nursing* (Simla: St. John Ambulance Association. 1913. Pp. 194), Major R. J. BLACKHAM, C.I.E., R.A.M.C., has succeeded in compressing a very large amount of information, adapted to the syllabus of the St. John Ambulance Association. All the matters that are likely to come under the notice of the nurse are dealt with, and the directions are clear and concise. It may be safely recommended.——We noticed the issue of the same author's *Indian Manual of First Aid* in THE LANCET so recently as June 7th, 1913, and now we have before us the fifth edition (Calcutta: Thacker, Spink, and Co. 1914. Pp. 189). The exhaustion within a year of four editions says all that need be said as to the usefulness of the book. The present issue is increased in size by some 15 pages, and several new illustrations have been added. The book is now the official text-book of the Indian Branch of the St. John Ambulance Association, and will be the standard book for all ambulance competitions in India. An Urdu translation has been issued, and translations into other Indian vernaculars are nearly ready.

With the possibility or otherwise of successful invasion of England by Germany and the abstract side of the question of voluntary *versus* compulsory military service, as discussed in *A German Invasion* (London: P. S. King and Son. Pp. 52. Price 1*s.*), by Mr. HENRY SEWILL, M.R.C.S., we do not feel called on to deal; the last few pages, however, deal with social problems as affecting the subject, and the author expresses satisfaction with our condition as compared with that of other countries in regard to the falling death-rate and the reduction in infant mortality. He considers (in which many will not agree with him) that our educational system is proceeding on right lines, and that in the promotion of public health a most urgent factor is slum abolition, in which he will command more general assent, and he deplores the evil effects on the race that must follow a blind system of artificial selection by the voluntary limitation of families.

JOURNALS AND MAGAZINES.

Journal of Pathology and Bacteriology. (Official Organ of the Pathological Society of Great Britain and Ireland.) Vol. XVIII., No. 3. Published from the Department of Pathology, University of Cambridge. Price 7*s.* 6*d.*; yearly subscription £1 1*s.*—Stuart McDonald and W. T. Sewell contribute a note on Malakoplakia of the Bladder and Kidneys in a girl, aged 24, who suffered from renal symptoms, and in whom a perirenal abscess due to B. coli was found. After death there were found in the kidneys and bladder tumours of the type to which v. Hansemann has given the name of malakoplakia. This is the first recorded case in which the kidney has been affected, and the authors suggest that the condition is due to the presence of certain cell-rests of developmental origin, which have been stimulated to activity and have degenerated, possibly under the influence of B. coli.—In a paper on the Technique of Cultivating Adult Animal Tissues *in Vitro*, and the Characteristics of such Cultivations, A. J. Walton describes fully the Carrel technique of the cultivation of the spleen, thyroid, kidney, testicle, and liver of the adult rabbit. The cultivations were successful in practically all cases.—J. W. M'Nee records a number of experiments on hæmolytic icterus. He notes that, as the result of their experiments on the effect of AsH_3 on geese whose livers had been removed, Minkowski and Naunyn in 1886 came to the conclusion that the liver is essential for the production of jaundice, and that true hæmolytic jaundice cannot occur. M'Nee, repeating their experiments, concludes that while it is uncertain whether true hæmolytic icterus can occur, no marked jaundice occurs in geese as the result of the administration of AsH_3 after removal of the liver. This is due, he thinks, to the absence of the endothelial cells of v. Kupffer, which split off the iron part of the hæmoglobin molecule and set free the pigment portion. In dogs in whom jaundice has been produced by toluylendiamin the appearances presented by the endothelial cells of the liver are the same as those seen in geese poisoned by AsH_3. Allowing for the greater importance of the spleen in higher animals, the pathology of hæmolytic icterus is probably much the same in man and dogs as in geese.—W. Henwood Harvey describes a congenital fusiform aneurysm of the first part of the aorta in a young rabbit three months old.—Sheridan Delépine describes the arsenious acid-glycerin-gelatin (arsenious jelly) method of preserving and mounting pathological specimens so that they retain their natural colours, and the use of new forms of receptacles for keeping museum specimens, a method which he claims as superior to the Kaiserling potassium-acetate-glycerin method.—A. C. Houston, in a note on water storage and its advantages, replies to Myer Coplans' criticism of the storage method of water purification, contained in the *Journal of Pathology and Bacteriology*, Vol. XVII., p. 367.—Adam Patrick, in remarks on typhoid bacilluria, with a description of certain atypical coli-typhoid bacilli found in the urine in enteric fever, notes that in 6 out of 17 unselected cases of bacilluria occurring in enteric fever the bacilli present were not B. typhosus but atypical (somewhat unstable as regards their fermentative powers) members of a typhoid-coli group. In four out of the five cases where agglutination tests were performed, the bacilli were unaffected by stock antityphoid serum, but were clumped by the patient's serum.—E. E. Glynn, M. Powell, A. A. Rees, and G. L. Cox, in Observations upon the Standardisation of Bacterial Vaccines by the Wright, the Hæmocytometer, and the Plate Culture Methods, claim that the most scientific method of enumerating bacteria for vaccine purposes is by the use of some form of hæmocytometer chamber.[1] The ordinary chamber, 0·1 mm. deep, may be used, but one 0·02 mm. deep gives slightly better results; an optically plane cover-slip must be used, with a weak solution of carbol thionin as diluting and staining fluid. The results obtained are considerably more accurate than those given by the Wright method or than those obtained by the plate-culture methods. —R. A. Chisholm, in a paper on the Water Content of the Tissues in Experimental Nephritis, points out that acute and extensive necrosis of the renal tubules in the rat, whether produced by uranium nitrate, potassium bichromate, or potassium chromate, leads, when excess of Ringer's fluid is given intraperitoneally, to an excess of water in the kidneys, muscles, and subcutaneous tissues, and in these only, with the possible exception of the alimentary canal. He notes, too, that the presence of subcutaneous œdema is not a measure of the amount of water present in the muscles and subcutaneous tissues.—This number contains an obituary notice of Theodor Albrecht Edwin Klebs, and the Proceedings at the January meeting of the Pathological Society of Great Britain and Ireland.

---

[1] THE LANCET, April 11th, 1914, p. 1023

British Journal of Inebriety.—The April number is mainly devoted to articles dealing with the treatment of the inebriate, and more particularly the male inebriate, from the point of view of institutional management. The Rev. S. Scobell Lessey, M.D., Chaplain-Superintendent of Abbotswood House, lays special stress on the value of religious influence as the most effective psychotherapeutic agency in the cure of intemperance. In the institution under his charge, where this influence is relied on to the practical exclusion of any other, he claims that from 50 to 60 per cent. of the cases which have passed through his hands have been permanently benefited. The application of this method presupposes, of course, the willing coöperation of the patient, and Dr. Lessey is very definitely of opinion that without such coöperation nothing can be done to cure inebriety. Amongst the practical difficulties which interfere with the successful management of inebriate homes Dr. Lessey especially notes the lack of means for dealing with refractory and undisciplined patients, and he expresses the hope that power may eventually be given to transfer such patients to a State institution with a more penal *régime*, as is done now in the case of drunkards committed to retreats under the provisions of the Act of 1898.—Mr. J. W. Astley Cooper supports Dr. Lessey's demand for larger penal powers for dealing with incorrigible and troublesome patients. and also demands that the present principle of ordering institutional treatment for specified periods should be abandoned in favour of a system of detention until cure. It hardly seems quite consistent with this view that Mr. Cooper should maintain, as he does, that the coöperation of the patient is one of the main principles on which the successful institutional treatment of inebriety must depend.—In contrast with the advocates of compulsory methods, Dr. Francis Hare describes the free system followed at the Norwood Sanatorium as avoiding some of the most serious difficulties met with in the management of patients under enforced detention; and Dr. H. Crichton Miller, in a brief but interesting paper, argues that the various methods proposed for treating the inebriate are fundamentally alike, though their advocates may not recognise the fact, in that they all aim at bringing about a readjustment of the psychic mechanisms underlying habit.

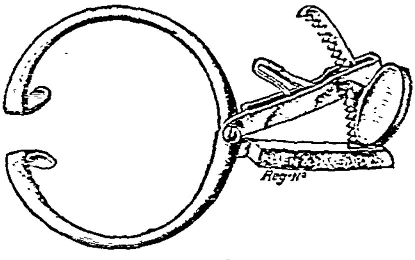
ROYAL STATISTICAL SOCIETY.—At an ordinary meeting of this society on Tuesday, May 19th, at 5 P.M., at the Surveyors' Institution, 12, Great George-street, S.W., a paper on Suggestions for Recording the Life History and Family Connexions of Every Individual will be read by Mr. Walter Hazell.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce the publication of a new work on "Operative Surgery: the Head and Neck, the Thorax, and the Abdomen," by Edward H. Taylor, professor of surgery in the University of Dublin. All the illustrations, 300 in number, are from original drawings, many being in colours. The same firm also announce new editions of the "Practice of Medicine," by Frederick Taylor, M.D., F.R.C.P. (tenth edition, thoroughly revised, with many new illustrations and skiagrams); "A Manual of Bacteriology," by R. Tanner Hewlett, M.D., F.R.C.P., D.P.H. (fifth edition, with 69 illustrations); and "Elementary Practical Chemistry," Part II., by F. Clowes, D Sc. Lond., and J. Bernard Coleman, A.R C.Sc. Dub. (seventh edition).—Messrs. John Bale, Sons, and Danielsson, Limited, announce the forthcoming publication of "The Problem of the Nations: A Study in the Causes, Symptoms, and Effects of Sexual Disease, and the Education of the Individual Therein," by A. Corbett-Smith, M.A. Oxon., editor of the *Journal of State Medicine.*—Messrs. P. Blakiston's Son and Co., Philadelphia, announce the forthcoming publication of a practical work dealing with the ills engendered by the vocations and avocations of all classes of society. The book will be under the joint editorship of Dr. George M. Kober, of Washington, D C., and Dr. W. C. Hanson, of Boston, Mass. Among the contributors are Sir Thomas Oliver, Dr. T. M. Legge (London), Dr. Teleky (Vienna), Dr. Devoto (Milan), Dr. Edsall (Harvard), and Dr. Alice Hamilton (Chicago).

New Inventions.

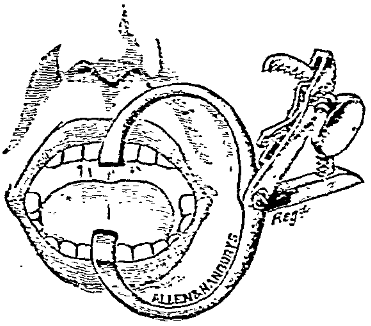
NEW MOUTH GAG.

THE accompanying illustrations show a mouth gag which is specially adapted for ear and throat surgeons and for the dental profession, but can be used in all cases where a gag is required. The improvements over existing ones are: (1) the limbs of the cheek portion are long, the joint being set well back—an essential in easy enucleation of the tonsils by Sluder's method; (2) the ratchet method of opening gives great force, with a gradual yet rapid opening of the mouth, a desideratum when operating without an anæsthetic: there is also less danger of breaking or extracting the teeth; (3) there are no projections, as the thumb piece which operates the ratchet is provided with a tumble joint, permitting it to lie flat against the cheek; and (4) the alveolar projection is at an acute angle so that it enters the mouth between the incisor teeth at right angles to them, giving the gag a firm hold with less tendency to slip than is usually the case.



The mouth gag.

My thanks are due to Messrs. Allen and Hanburys, Limited, of Wigmore-street, London, W., for the manner in which they have carried out my suggestions in the construction of the instrument.



The mouth gag in use.

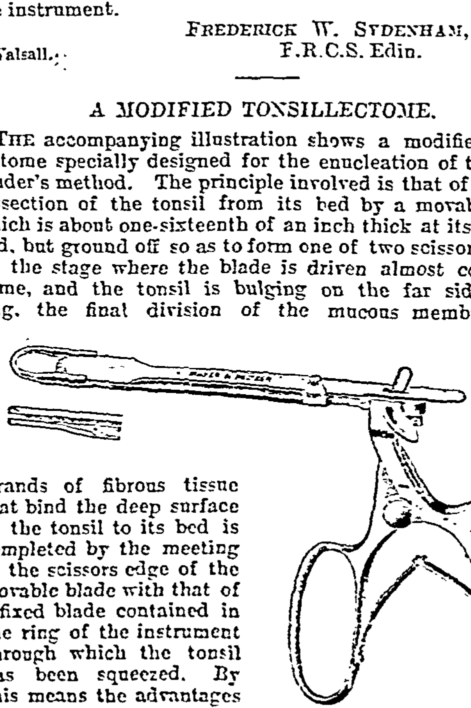
Walsall.

A MODIFIED TONSILLECTOME.

THE accompanying illustration shows a modified tonsillectome specially designed for the enucleation of tonsils by Sluder's method. The principle involved is that of the *blunt* dissection of the tonsil from its bed by a movable blade which is about one-sixteenth of an inch thick at its tonsillar end, but ground off so as to form one of two scissors blades. At the stage where the blade is driven almost completely home, and the tonsil is bulging on the far side of the ring, the final division of the mucous membrane and strands of fibrous tissue that bind the deep surface of the tonsil to its bed is completed by the meeting of the scissors edge of the movable blade with that of a fixed blade contained in the ring of the instrument through which the tonsil has been squeezed. By this means the advantages of blunt dissection are preserved, yet cutting blades are provided at the very



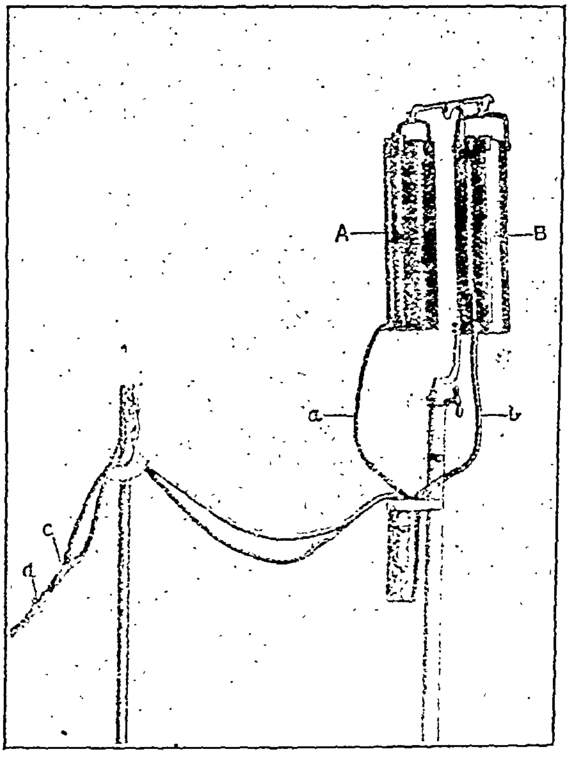
moment they are required, and the tonsil comes away at once in the instrument without any twisting and pulling whatever. The hæmorrhage is only slight, and this is probably explained by the fact that the vessels, being first stretched and then cut across by scissors blades, have their lumens occluded much in the same way that the bore of a rubber drainage tube is closed by cutting it with a pair of scissors. The blade portion comes apart readily into three pieces—the blade itself, the bed in which it travels, and the spring (which controls the blade, holds the tonsil after removal, and locks the parts together). It is thus easily cleaned and sterilised. This instrument, which I have used in a large number of cases with perfectly satisfactory results, can be fitted with a handle giving either the Heath or the Mackenzie position.

It has been made for me by Messrs. Mayer and Meltzer, of Great Portland-street, London, W.

Edinburgh. K. G. HEARNE, M.B. Edin.

A SIMPLE APPARATUS FOR SALINE INFUSION DURING HEDONAL ANÆSTHESIA.

THE following is a description of a modification of Page's well-known apparatus for administering hedonal to enable normal saline to be substituted for the hedonal solution during the operation with a minimum of trouble to anæsthetist and patient. To the hedonal stand is added a second cylinder of the Page type, labelled "Saline." This is fitted with tubing and glass dropper. It is attached to the hedonal system by a Y-shaped glass tube (*c*). From the common limb of the Y a single tube connects with the cannula, so serving to convey fluid from either cylinder into the vein. On this common tube is a two-way tap (*d*), with a side opening leading to the exterior. By adjusting the tap the stream from the cylinders may be temporarily diverted through this lateral opening. The object of this manœuvre will shortly be apparent. During the induction and early stages of anæsthesia the saline system is shut off by keeping the cylinder tap closed. When it is desired to substitute normal saline for the anæsthetic fluid the two-way tap (*d*) is adjusted so that the stream passes through the lateral opening, the hedonal cylinder tap is closed, and the saline cylinder tap is opened. By this means all the air previously present in the saline system is expelled through the lateral opening of the two-way tap. When this has been accomplished, this tap has only to be readjusted and the saline is now flowing through the cannula into the vein. Should the patient require more of the anæsthetic at any period of the operation the process is simply reversed.



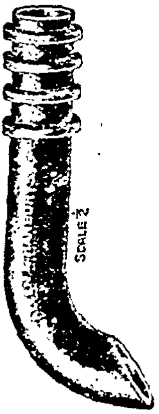
A, Hedonal cylinder. B, Saline cylinder. *a*, *b*, Tubing and glass dropper attachments. *c*, Y connexion. *d*, "Two-way" tap.

The accompanying figure illustrates the apparatus in use. It has been found very satisfactory in practice at Great Ormond-street, and has been made for me by the Holborn Surgical Instrument Company, Thavies Inn, Holborn-circus, London, E.C.

T. TWISTINGTON HIGGINS, M.B., B.Ch. Vict., F.R.C.S. Eng.

Hospital for Sick Children, Great Ormond-street.

A NEW COLOSTOMY TUBE.



A NOT uncommon result of the operation of colostomy performed either with or without the aid of a Paul's tube for cases of acute intestinal obstruction is that the colostomy fails to act for a period varying from a few hours to several days, and in a few cases may even fail to act at all. The various remedies—e.g., eserin, pituitary extract, &c.—commonly employed usually have little or no effect, and even the removal of the Paul's tube often yields the same negative result. Dilatation of the colostomy by means of a finger inserted into the bowel usually gives temporary relief, but in a certain number of cases the abdomen becomes more and more distended, the patient suffers increasing pain, and finally dies. This failure of the colostomy to act may to a small extent be due to paralysis of the distended intestine, but I think it is mainly due to an obstruction produced by a kinking of the bowel just as it leaves the abdominal cavity. To overcome this difficulty I have recently been using a curved colostomy tube which is introduced into the interior of the bowel, and when in position extends beyond the site of the kink and prevents any obstruction at that point. It is used in the following way. After the wound has been sutured and the projecting loop of intestine isolated by gauze, a purse-string suture is inserted into a portion of the intestinal wall and an opening made in the centre of bowel wall thus enclosed. The curved end of the tube is then inserted into the opening and pushed into the lumen of the proximal limb of the loop of intestine until the whole of the curved portion has passed through the abdominal wall. Care should be taken to rotate the tube so that the internal or proximal orifice faces the direction of the flow of intestinal contents. The purse-string suture is next tied tightly over one or more of the four flanges provided for the purpose, and a curved glass junction with rubber tubing is fixed to the outer or distal orifice of the tube. The rubber tubing can subsequently be led into a receptacle at the side of the bed. Gas and liquid fæces usually escape at once, but should this not occur, the introduction of two or three ounces of glycerine through the tube into the bowel will produce an evacuation of intestinal contents within a few minutes. The colostomy tube is removed about the fourth or fifth day when the purse-string suture sloughs out. The tube is made of rubber to minimise the possibility of pressure ulceration of the bowel within the abdominal cavity. The internal diameter measures half an inch, and is sufficiently large for the passage of the liquid contents of the intestine in cases of acute obstruction.

Messrs. Allen and Hanburys, Limited, of Wigmore-street, London, W., have made the tube for me.

St. Thomas's Hospital, S.E. B. C. MAYBURY, F.R.C.S. Eng.

ROYAL DEVON AND EXETER HOSPITAL.—At the meeting of the governors of the Royal Devon and Exeter Hospital which was held last week it was decided to erect a new wing to provide accommodation for the nursing staff. The approximate cost of the scheme was stated to be £5900, but it is hoped that the expenditure will be reduced by a modification of the plans.

"THE CHANCELLOR"

Genuine Pure Grape

BRANDY.

Extract from THE LANCET, May 9th, 1914:—

"We have submitted this brandy to analysis, and the results support the claim that it is a pure grape spirit. ...... Although not produced in the Cognac district, it possesses similar characteristics to the products of the Charente. It is mellow, and free from crude products. ...... It comes well out of comparison with the matured spirit produced from wine distilled in the Cognac district."

The Prevention and Treatment of Tuberculosis in London.

WE have received the report of an inquiry by the Charity Organisation Society in regard to the prevention and treatment of tuberculosis in London. After reference to the confusion which had resulted owing to action taken by several bodies directly interested in the matter, especially the Local Government Board, the London County Council, the London Insurance Committee, and the Metropolitan Asylums Board, a review is taken of the various factors which created the situation that had arisen when the inquiry was commenced. The foremost of these factors was the provision of treatment under the Insurance Act in cases of tuberculosis. The second factor, of scarcely less importance, was the Order of the Local Government Board of November, 1911; by this Order sanitary authorities were empowered to treat pulmonary tuberculosis in the houses of the patients, and were invited in a circular letter to form schemes with this object. The third factor was the publication of the Interim Report of the Departmental Committee on Tuberculosis in April, 1912, and of the Final Report in March, 1913. These were the three chief points in the position when the Charity Organisation Society decided upon its inquiry. After careful consideration it was arranged to take the report of the Departmental Committee as a basis, and to apply the test of their recommendations to the existing condition of affairs in London, in order to discover how far their proposals had been carried out, how far the present machinery rendered this possible, and what prospects there were that any defects discovered would be remedied.

The dispensary being the central feature of the recommendations of the Departmental Committee, visits were paid to dispensaries of different types now at work in London. An interesting account is given of the work carried out by these institutions, and then the position in London with regard to the provision of sanatoriums, hospitals, and other institutions in which tuberculosis can be treated is considered. An account is next given of the negotiations by public authorities which took place in 1912–13; the whole course of events illustrates in a remarkable way the dangers and difficulties involved by divided authority. Finally, the conclusions arrived at by the Charity Organisation Society as the result of the inquiries are recorded. This body has warmly supported from the first the adoption in London of what is now known as the dispensary system for the prevention and treatment of tuberculosis. The society has had long experience in dealing with tuberculosis among working people, and is convinced that no measure of attack upon the disease has any chance of success unless it begins and ends with the home. Unless the patient is followed there and both he and his surroundings are adequately dealt with, the provision of treatment in institutions or by other means is futile. We have repeatedly expressed the opinion that the eradication of tuberculosis is inextricably bound up with betterment of the housing of the working-classes. We must keep this in view, but unless suitable and practical instruction is afforded and supervision is supplied to see that that instruction is carried out, the value of sanatorium and hospital treatment will be very seriously diminished. It is the opinion of the Charity Organisation Society that in order to secure elasticity of working the dispensary should be a voluntary institution. Voluntary institutions certainly have great advantages over municipal ones, and we agree that the strongest argument against the latter, as at present conducted, arises from the circular of the Local Government Board of Dec. 6th, 1912. This circular states: "It is not, in the Board's view, desirable that the dispensary officer should undertake ordinary domiciliary treatment," and, further, "in the case of insured persons the cost of domiciliary treatment will be paid out of the funds of the Insurance Committee, in other cases by the patient or someone acting on his behalf." If uninsured persons are not satisfactorily treated in their own homes in the same manner as the assured, naturally the fight against the disease is materially weakened. The financial difficulty, however, at once arises. Whence are the funds for voluntary dispensaries to be derived? Subscriptions, and especially donations to the special hospitals, show a considerable falling off since the introduction of "sanatorium benefit." The taxpayer naturally objects to contribute both ways. But, on the other hand, there are difficulties in the opposite direction, which to some extent support the society's view. The local boroughs are already finding great difficulty in obtaining financial assistance from the Insurance Committee in order to pay the salaries of the medical officers attached to the municipal dispensaries, and their resources are considerably hampered thereby. The reason given for the refusal is, we are informed, that the duty of seeing the patients in their own homes falls upon the doctors on the panel. The committee seems to have lost sight of the fact that special experience is required, especially in regard to diagnosis and the examination of contacts, and we entirely agree with the point emphasised in the report that it is essential that the medical officer in charge of the dispensary should visit the homes of the patients, and naturally the Insurance Committee should contribute towards the salary of that officer.

With regard to dispensaries as departments of

Annotations.

"Ne quid nimis."

RECENT RESEARCHES ON YELLOW FEVER IN WEST AFRICA.

THE subject of yellow fever has of late attracted considerable attention, particularly in view of the possible danger of the extension of the infection after the opening of the Panama Ship Canal. The endemicity of the disease in certain defined areas is well known, and among those which specially concern this country is that part of the West African Coast situated between the French territory of Senegal on the north and the German Cameroons on the south. In this region are situated the four British colonies of the Gambia, Sierra Leone, the Gold Coast, and Southern Nigeria, from which the Colonial Office has been collecting information in a systematic way in recent years in order to throw light if possible upon the problems connected with this grave malady. Hitherto investigations concerning it have been hindered by the absence in many cases of any positive clinical symptoms, or definite post-mortem appearances in fatal cases whereby the presence of the disease could be demonstrated beyond a doubt. So long as no specific organism could be recognised, the diagnosis in disputed cases could not be settled satisfactorily. In view of the importance of the subject the Secretary of State appointed a small Commission of experts, of which Sir William Leishman and Sir Ronald Ross are members, to examine and study the evidence collected from our colonies and to advise as to the directions in which further investigations might usefully be made. Taking advantage, in 1913, of an outbreak of what seems to have been undoubtedly true yellow fever in Lagos and other places in Southern Nigeria, Dr. J. W. Scott Macfie and Dr. J. E. L. Johnston, of the West African Medical Staff, conducted a series of experiments and observations at the Institute for Medical Research at Yaba, near Lagos, and their results have now been published in the current number of the *Yellow Fever Bureau Bulletin*, Vol. III., No. 2.[1] These investigators carefully examined the blood of the persons attacked, and in practically every instance they found in the red corpuscles certain bodies indistinguishable from those described in 1909 by Dr. Harald Seidelin and discovered by him in the blood of yellow fever cases in Yucatan, to which he has given the name of paraplasma flavigenum. Experimental animals, such as guinea-pigs, dogs, and rats, were successfully inoculated in the Yaba Institute from human cases; and of 11 stray native dogs sent from Lagos for examination two were found to have the paraplasma "bodies" in their blood—instances, it is believed, of the infection naturally acquired. Guinea-pigs could be inoculated with success as late as the eighth day of the disease. In some human cases these yellow fever "bodies" were found in the circulation some days after the fever had subsided and when the patient to all appearances was convalescent. Dr. Macfie and Dr. Johnston believe that the paraplasma is the specific parasite of yellow fever and capable of infecting the stegomyia fasciata, the insect transmitter of the disease to man. Dr. Seidelin, we learn, has had an opportunity of examining some of the blood films from Lagos and has confirmed the presence in them of the paraplasma flavigenum. Before these results are accepted by the scientific world they will have to be repeated and confirmed by other competent experts, and should the experiments be repeated with success it is obvious that a very great advance will have taken place in our knowledge of the disease. It will then be possible to apply a bacteriological test in all doubtful cases; it will also be possible to study the life-history of the yellow fever parasite in its vertebrate and invertebrate hosts; moreover, the therapeutic value of remedies for the disease can then be properly studied. It was, we believe, Sir Patrick Manson who first suggested that the endemicity of the malady might be associated with the occurrence of the infection in one or another of the lower animals. Suspicion has been attached in Lagos to dogs and perhaps to rats in this capacity. In THE LANCET of April 25th Dr. Andrew Balfour suggested the possibility of a certain species of monkey in Trinidad acting there as a reservoir of the virus. It is possible that different animals in different localities may upon occasion foster the endemicity of yellow fever. In the same way in plague, for instance, the rat is responsible in India for keeping a locality infected, the tarabagan in Mongolia, the spermophile in the region between the rivers Volga and Ural, and the ground squirrel in California. No doubt the expert Commission appointed by the Colonial Office will without delay examine the evidence and make a pronouncement on the subject, and this will be anxiously awaited by all who are interested in yellow fever. We are aware that the validity of the claims of Dr. Seidelin to have discovered the parasite of this disease is emphatically rejected by some, in particular by Dr. A. Agramonte, of Cuba, who was a member of the famous commission appointed by the United States Government in 1900, and which did so much to throw light upon the disease and its prevention. Dr. G. C. Low, of the London School of Tropical Medicine, seems also to throw doubt upon the existence of the paraplasma flavigenum as a definite organism.[2]

HEALTHY MENINGITIS CARRIERS.

EPIDEMICS of cerebro-spinal meningitis occurred from 1875 to 1877 in Norway, and 704 cases of the disease with 247 deaths were reported. The town of Christiania escaped these visitations almost entirely; indeed, only 10 instances of cerebro-spinal meningitis occurred there between the years 1866 and 1910. In 1911 there were 8 cases; in 1912 an epidemic of 200 cases occurred, with 13 deaths. The cause of this visitation remained obscure; it was most severely felt in the most densely populated part of the town, and only in a few instances was there more than a single case of meningitis in a family. Twenty-four of the patients were less than 1 year old, and 83 were between 2 and 5 years of age. It was thought that the spread of the epidemic must be due to healthy carriers of the meningococcus. Accordingly steps were taken from the very beginning of the epidemic to obtain swabs of the pharyngeal mucus from members of the families in which cases of meningitis occurred, in the hope of discovering meningococcus carriers. Ustvedt and

[2] THE LANCET, May 9th, 1914, p. 1357.

Diesen[1] describe the way in which this work was carried out at the laboratory of the Board of Health in Christiania; in all, 797 examinations were made, but the meningococcus was found no more than four times. This result is in direct opposition to the observations made in Silesia and Western Germany during epidemics of cerebro-spinal meningitis, although, as the authors point out, many other observers have reported instances in which no carriers of the coccus have been found in families in which cases of meningitis were occurring.

CHOLECYSTITIS WITHOUT STONES OR JAUNDICE IN ITS RELATION TO CHRONIC PANCREATITIS.

IN the *American Journal of the Medical Sciences* for April Dr. William J. Mayo has published an important paper on cholecystitis without stones or jaundice in its relation to pancreatitis. As he points out, cholecystitis without stones is comparatively common, and of late has come into prominence. The types vary from the mild chronic catarrhal to those characterised by necrosis and perforation. Some uncertainty exists as to when chronic cholecystitis should be considered surgical. It is not infrequently associated with *chronic* appendicular infections, especially when accompanied by *stercoliths*. Whether the appendicular infection is the cause of the cholecystitis has not been determined, but it seems possible as bacterial or toxic products are carried in the portal veins to the liver and there destroyed or excreted in a modified form in the bile. The diagnosis of cholecystitis, even when stones are present, is *not easy*. With the palm an area may be covered which could be involved in pyloric or duodenal ulcer, disease of the gall-bladder, appendicitis, or affections of the right kidney and ureter. Chronic cholecystitis produces two types of gall-bladder: 1. The large, blue, distended gall-bladder which is not emptied by compression. The bile is thin and often fœtid from colon infection. 2. The thick-walled whitish gall-bladder, which is often adherent and usually contains thick and tarry bile with much mucus. In many cases the gall-bladder appears to be normal. As a rule enlarged glands along the common duct can readily be detected. In some cases enlargement of the lymphatics is the only sign that the gall-bladder is probably diseased. It may not be possible to determine the existence of cholecystitis until the gall-bladder is opened. Even then the diagnosis may remain doubtful until the gall-bladder or a portion of its mucous membrane is submitted to a pathologist. Fortunately the "strawberry gall-bladder," which shows *yellow* specks (the bases of villi denuded of epithelium and stained with bile), is one of the *most* frequent types. Here radical operations give as high a percentage of cures as in cases of gall-stones, or a higher percentage. But the milder degrees of cholecystitis do not give a high percentage of cures and should be considered medical rather than surgical cases. While cholecystotomy is an efficient procedure in gall-stone disease when the gall-bladder is normal and the ducts free, it is not satisfactory in cholecystitis. Cholecystectomy, Dr. Mayo holds, is largely indicated in gall-stone disease and in practically all cases of cholecystitis. If so much uncertainty exist with regard to infections of the gall-bladder, how much more must exist in infections of the pancreas. The sense of sight cannot aid, as in the examination of the mucosa of the gall-bladder. The diagnosis must be established by the sense of touch and a certain amount of "intuition." For many years Dr. Mayo has made it a practice to examine the entire contents of the abdomen with the gloved hand whenever it is opened for any purpose and the condition of the patient permits. He has been surprised to find how frequently the pancreas shows enlargement, induration, and nodulation, which would have justified a diagnosis of chronic pancreatitis if some disease of the biliary system had been the original lesion, but in which there were no symptoms whatever of pancreatic inflammation. In the routine of the Mayo Clinic several hundreds of stools have been examined in cases of chronic pancreatitis for signs of pancreatic insufficiency. These were rarely found either in cholecystitis or in cases of gall-stones. Hence statistics of the relative frequency of pancreatitis must be accepted with reserve. Yet that chronic pancreatitis does exist, and that it occurs most frequently in connexion with infections of the biliary tract is established. There is a group of cases of chronic cholecystitis without gall-stones or jaundice accompanied by chronic interlobar pancreatitis. There is neither dilation of the common duct nor distension of the gall-bladder. These cases are treated by drainage of the biliary tract, although there is no evidence of back pressure. The fact is disregarded that it is infection of the gall-bladder which has caused the disease of the pancreas, and that this infection probably will not be cured by drainage. In such cases Dr. Mayo holds that the gall-bladder should be removed if it shows evidence of chronic cholecystitis, especially of the "strawberry type." When he did cholecystotomy he found that the patients were relieved during drainage, but the symptoms returned when the fistula closed. Subsequent cholecystectomy cured the patients.

PURPURA VESICÆ AND SIMPLE ULCER OF THE BLADDER.

THE *Wiener Medizinische Wochenschrift* of March 28th is devoted almost entirely to urological subjects, and contains a number of papers by former pupils and assistants of Professor Anton Ritter v. Frisch in honour of the twenty-fifth anniversary of his appointment as chief of the urological section of the Vienna Polyclinic. Among these papers are some of considerable interest, giving the experience of the Viennese urologists in regard to vaccines and other methods of treatment. Dr. v. Blum contributes an interesting paper on simple ulcer of the bladder, in which an ingenious theory of its pathogenesis is propounded. He maintains that acute hæmorrhagic cystitis and simple ulcer of the bladder have not received the attention they merit, and he proposes to substitute the name of purpura vesicæ for the former of these as more truly indicating its nature. He states that for some years he has been familiar with a form of acute cystitis with the following features occurring both in men and women. Sometimes the onset is quite sudden, not infrequently as a sequel of some acute catarrh of a mucous membrane, such as coryza, influenza, or tonsillitis. There is usually a short febrile period, with dysuria, strangury, and severe frequency. The end of the act of micturition is painful and is associated with the passage of a few drops of blood-stained urine. The main part of the urine may be clear and apparently free from blood, but as a rule it contains a relatively high amount of albumin. In the sediment there are a few red blood corpuscles and large quantities of bladder epithelium. On bacteriological examination the urine may be sterile or it may contain bacillus coli communis, or streptococci and staphylococci. If the bladder be examined cystoscopically at this stage multiple hæmorrhages are found distributed over the whole of its inner surface. If no treatment has been carried out, the appearances alter in a few days and the hæmorrhagic areas develop into definite ulcers, at first covered with membrane and subsequently granulating. The hæmorrhagic cystitis has developed into a membranous and ulcerative cystitis. At this stage the urine becomes turbid, brownish-red in colour, and contains in the sediment erythrocytes, pus cells, bladder epithelium, and crystals. Dr. v. Blum maintains that if a solitary ulcer originating in this manner were seen it would be regarded as a simple ulcer of the bladder. If such an ulcer becomes chronic its edges become hard, prominent, and callous, and they may become encrusted with a phosphatic deposit. Purpura vesicæ appears to be more common at certain seasons—namely, the spring and autumn. The relationship between simple ulcer and hæmorrhagic lesions of the bladder was affirmed as long ago as 1901 by Le Fur, who also suggested an analogy between these vesical ulcers and ordinary gastric ulcer. Dr. v. Blum carries this analogy a stage further, since he suggests that the vesical ulcers are produced as a result of the digestive action of the urine upon the damaged areas of mucous membrane. It has long been known that the urine may contain definite amounts of ferments, particularly of pepsin, and Grober demonstrated that the latter was combined with hydrochloric acid. Dr. v. Blum claims in support of his theory the beneficial effects of keeping the urine alkaline in the treatment of chronic simple ulcer of the bladder. He asserts that this form of treatment, combined with local measures and with attempts to disinfect the urine, leads to rapid healing even in chronic ulceration, and also acts as a preventive in cases seen in the hæmorrhagic stages. The beneficial effect of the alkalies he explains as being due to their power of inactivating pepsin, and thus preventing its digestive action on the damaged areas.

FRACTURE OF THE CARPAL CUNEIFORM BONE.

Dr. W. P. Coues has described in the *Boston Medical and Surgical Journal* of April 9th a very rare form of fracture—isolated fracture of the carpal cuneiform bone. This injury contrasts with fracture of the scaphoid bone and dislocation of the semilunar bone, which have been described ever since the advent of the X rays. A woman, aged 23 years, while doing gymnastics—standing on the hands—turned too far, lost her balance, fell to the ground, and rolled over on her left hand, which was flat and extended on the ground. She immediately felt pain in the wrist and was unable to use the hand. She said that she also felt crepitus at the time. On the next day the hand was very lame and there was ecchymosis over the dorsum. She consulted a practitioner, who thought there was no fracture. Disability, felt most on rotation of the wrist and extension of the hand, persisted. At first the pain was constant, then it was felt only when attempting to do gymnastic work. She was seen by Dr. Coues about three months after the accident. Of late she had felt numbness in the hand and arm. On examination there was no obvious swelling or ecchymosis in the region of the cuneiform bone, but flexion and extension of the wrist were slightly painful there and active abduction was more painful. Forced passive abduction caused great pain. Rotation of the forearm caused pain in the region of the cuneiform bone and a little lower. Slight synovitis of the middle extensor tendon was present. When the patient picked up a weight or turned a door-handle pain was felt in the cuneiform region. Pressure over the cuneiform bone was very painful, but no crepitus was elicited. Lateral pressure across the wrist so as to make the pisiform bone press upon the cuneiform caused much pain. A skiagram showed an incomplete fracture of the cuneiform bone running from the ulnar side about half way across the bone obliquely. The hand was placed on a palmar splint and a pad and strapping were applied over the cuneiform bone. After a few days there was considerable relief, and then the improvement continued, but was slow. A radiogram taken after immobilisation for a month showed no bony union, though the pain and disability were less. Another radiogram taken ten days later showed considerable union. The splint was removed and the hand bandaged. Complete recovery ensued. The long period of immobilisation before union took place was evidently due to the length of time during which the patient had attempted to work with the fracture ununited.

THE CAUSE OF LANDRY'S PARALYSIS.

THE causal agent of Landry's paralysis has been the subject of numerous observations, and though much debated is still a matter of dispute. A fatal case of the disease is recorded in the *Berliner klinische Wochenschrift* of April 27th by Dr. Erich Leschke, together with some interesting experiments carried out to discover the organism causing the condition. The patient was a girl, aged 16 years, who was taken ill on Dec. 17th, 1913, with an acute ascending paralysis. About 14 days previously she had complained of a trivial cold. The paralysis commenced with slight weakness in the hands, and on the second day there was complete flaccid paralysis of both lower extremities. The patient was then seen by Dr. Alfred Saenger, of Hamburg, and transferred to a hospital in that city under his care. On Dec. 20th the paralysis had involved the buttocks and both arms, while the breathing was becoming increasingly difficult. Death occurred on Dec. 21st with paralysis of the vagal and vaso-motor centres. A necropsy was made 16 hours after death, and macroscopically no changes were found in any of the organs. On microscopical examination of the nervous system recent and severe changes were found in the ganglion cells, and more or less complete plasmolysis and chromatolysis of the cells of the anterior horns of the spinal cord. No inflammatory changes of any kind were found. In fresh teased preparations of the spinal cord and also in stained sections Dr. Leschke was able to demonstrate very fine bodies 0·1 to 0·2μ in size. They were for the most part intracellular, but were sometimes to be seen outside the cells. They could be stained in teased preparations with methylene-azure, Giemsa, or carbol-fuchsin. To demonstrate them in the sections Dr. Leschke employed the following method. The section was stained with concentrated carbol-fuchsin for about a minute and then carefully decolourised in a pale yellow solution of picric acid in absolute alcohol, until practically only the cell nuclei and red corpuscles remained coloured. On careful examination the "Landry bodies" could be seen as sharply defined red objects. Attempts to transmit the disease to rabbits and guinea-pigs were unsuccessful. Similar attempts with monkeys (Macacus rhesus) gave positive results. Portions of the fresh spinal cord removed at the necropsy were rubbed up with normal saline solution and injected intraspinally and intraperitoneally. The injection was made into one monkey on Dec. 22nd, 1913. It remained well until Dec. 31st, but died suddenly next night. In all Dr. Leschke succeeded five times in transmitting the disease to monkeys either from the spinal cord of the patient or from that of an infected monkey. The incubation period varied from 7 to 23 days. In two of the monkeys he was able to observe the course of the disease. They were attacked by an acute paralysis and lay quite flaccid, dying within a few hours of the onset. At the necropsy of these monkeys no gross changes could be found, but in all cases teased preparations showed the characteristic bodies in the ganglion cells or in their vicinity. Further observations showed that the Landry virus was a filter passer, that it was capable of cultivation, and that such cultures were capable of conveying the disease to monkeys. The cultures were obtained by Noguchi's method. Pieces of the spinal cord from the patient and from infected monkeys were inoculated into ascitic fluid and ascitic bouillon to which rabbit's or guinea-pig's kidney was added, under aerobic and anaerobic conditions. In the latter case some slight growth was apparent, but Dr. Leschke has not yet succeeded in obtaining a good progressive culture. His observations are of great interest, and should, if confirmed, go far to clear up the doubtful points in the etiolology and pathology of this obscure malady.

THE SERO-DIAGNOSIS OF CANCER.

THE work of Emil Abderhalden showed the presence of what he called "protective ferments" in the blood of animals, produced as a result of experimental stimuli and physiological and pathological conditions. A process taking place in the body which is, perhaps, harmful to the welfare of the individual, itself initiates or stimulates the production of antibodies whose effects are specifically directed to the removal of the deleterious agent. These antibodies occur in the blood serum; in relation to general infections they are familiar. But the far-seeing views of this distinguished scientist detected, as a result of his work on protein metabolism, an analogous mechanism in relation to metabolic changes the result of such effects as the growth of cancer and the onset of pregnancy. In other words, such processes initiate in the blood changes of essentially protective nature whose action is in many ways similar to that evoked by bacterial infection. But in one particular do the processes appear to differ. The protective substances are essentially digestive ferments and work on similar lines. The result of these observations has been to produce a test which has considerable value in the detection of cancer. In brief, it consists in testing the capacity of the blood serum of the suspected person to digest a given quantity of cancer protein. Strong powers of such digestion favour the diagnosis of malignancy: weak action negatives the probability. A series of cases has been tested in this manner by C. B. Ball, who records his results in a paper in the *Journal of the American Medical Association* (1914, Vol. LXII., p. 599). The cases are 51 in number. His results are certainly striking. The cases are classified into three groups. These, with the tests applied, showed the following figures. Positive tests, cancer; negative, no cancer:—

Cases.	Positive.	Negative.
Clinically malignant	7	0
Suspiciously ,, ...	20	8
Clinically non-malignant ...	4	12

The value of observations of this nature depends essentially upon the accuracy of the diagnosis and later confirmatory evidence. In this series care has been exercised. We are told that all the 20 positive suspicious cases were verified later as cancer either by Roentgen rays in 3, post-operative microscopy in 10, and definite subsequent history in 7. In the 8 negative suspicious cases there were two errors: one was a uterine tumour, but microscopic examination failed to show cancer tissue; the other proved to be a case of general miliary tuberculosis. In none of the other negative cases have suspicious signs developed. The four clinically non-malignant cases which gave positive reactions were all in pregnant women. In each of these cases the cancer tissue digested in the test was from a uterine growth. It has been found that pregnant serum may digest uterine tissue, and this helps to explain the divergence in the test from the rest, for in all the rest the cancer tissue was from other situations. Such a series of tests have considerable significance. There is the further possibility, suggested by allied observations to these serum reactions, that they may aid in roughly localising certain classes of tumour. It has been found that tumours of the genital tract may create a ferment capable of digesting ovarian, uterine, or placental tissues. Tumours from elsewhere in the body fail to do this. A positive reaction in such a case gives a probability of the site of the lesion. Extension of such responses may be anticipated, and it is thus suggested that there are grouped reactions, and that various sections of independent ferment-production seem to be governed by the difference of functional activity.

"THE FAMILY ENCYCLOPÆDIA OF MEDICINE."

WE are asked to give publicity to the following statement, which has been sent to us at the instance of the medical practitioners concerned:—"It will be recalled that the names of several professional men appeared in connexion with this work, and were advertised in such a way as to make it appear that these gentlemen were joint authors. The assistance was in fact gratuitous, and consisted in making corrections in the author's manuscript, and the use which was made of their names was without the knowledge or authority of the professional men concerned. The author has expressed his regret for this error, which caused the recognised rules of professional conduct to have been broken unwittingly, to the great regret of the gentlemen concerned. The author has undertaken that none of the names shall in future appear in connexion with this work, whether in book or part form. The publishers have likewise given their assent to this undertaking. It may be added, in explanation of the fact that the names reappeared in Parts 2 and 3, that these parts were already in print and Part 2 already distributed, and that the publishers did not see their way to reprint them. After fullest consideration of the question it was decided to seek the removal of the names by negotiation rather than by resorting to legal process."

A MEMORIAL TO DR. LUCAS-CHAMPIONNIÈRE.

A COMMITTEE has been formed to erect a monument to the memory of Dr. Just Lucas-Championnière. Knowing the admiration and sympathy of the English medical profession for their late illustrious colleague, the committee are convinced that his numerous friends in England would like to participate in this testimonial. A preliminary circular has been issued which states that the spontaneous demonstration of regret and admiration aroused by the death of Just Lucas-Championnière has manifested itself in a wish to erect a monument worthy of his memory. The committee, which includes a large number of his colleagues, pupils, and friends, has decided to open a fund, in which "those who knew the departed master, and who therefore must have loved him," are invited to participate. The composition of the committee is as follows:—President, Profesor Guyon; Vice-President, Professor Laveran; Secretary-General, Dr. Michon; Secretaries, Dr. Dagron and Dr. Le Marc-Hadour; Secretary-Treasurer, M. Georges Steinheil, who will receive subscriptions at his publishing house, 2, rue Casimir-Delavigne, Paris. We cordially endorse the committee's invitation to their colleagues in this country.

THE LOCATION OF THE TYPHOID BACILLI IN THE BODY OF THE CARRIER.

THE discovery of the typhoid carrier has raised new problems, not only in preventive medicine but also in the pathology of infection and immunity. Two interesting contributions that have just appeared in continental journals seem to carry us a little further into the heart of these unexplored territories. The first of these is a short note by Dr. E. Ebeling, published in the *Berliner Klinische Wochenschrift* for April 20th. In this is described the case of a woman who was infected with typhoid fever in 1900. From 1904 to the present time there have been cases of typhoid fever in her village or in neighbouring villages which have been traceable to milk or other foodstuffs supplied by her. These cases were 14 in number, and led to the infection of 18 others. Examinations of the stools and urine of the supposed carrier were, however, negative, until the lady's indiscrete boasting revealed the fact that the material which she had been sending for examination did not emanate from her at all. Her blood was accordingly taken and the Widal test applied, agglutination being secured with serum diluted 200 times. The chief point of interest in the case lies, however, in the fact that the typhoid bacillus was found in cultures made from the patient's blood, though she was apparently in perfect health at the time of the examination. The stools and urine also yielded cultures of the organism at this time. Five weeks later, however, the blood had become sterile, and the Widal reaction was less definitely positive. Another addition to our knowledge of these matters was contributed by Dr. Bela Purjesz in the *Wiener Klinische Wochenschrift* (No. 1, 1914). He studied a group of 20 cases, 15 of whom gave a positive and 5 a negative Widal reaction. In all these patients, or in most of them, cultures were made from the circulating blood, the stools, and the duodenal contents as recovered with an Einhorn tube. These examinations were made from one to four weeks after the temperature had become normal. The duodenal contents represent the immediate secretions of the gall-bladder, and were examined to see whether the bacilli might not be discoverable by this method in some of those cases in which examination of the stools was negative. The bacilli were found in the duodenal contents in 8 of 15 positive cases, but in only one of these was examination of the stools negative. As Dr. Purjesz points out, however, it is hardly fair to base conclusions on single examinations of a few cases, and he thinks that a wider application of the method might yield results that would show its possible value as a means of detecting the elusive carrier. But it is to be doubted whether the suspected person will regard the employment of the duodenal tube as an additional inducement to take a scientific interest in his own case.

THE CHINA MEDICAL MISSIONARY ASSOCIATION.

THE biennial meeting of the China Medical Missionary Association, which is the only body of qualified practitioners engaged in general medical work among the Chinese, will be held in Shanghai on Monday, Feb. 1st, 1915, and four following days. The undoubted success of the last meeting of the association held in Peking, when the President of the Chinese Republic officially welcomed the association, suggests that the forthcoming one will be equally well attended and profitable; it is estimated that at least a fourth of the 400 to 500 members will attend, and papers of a high order of merit are expected. Papers to be read will be printed as abstracts, thus allowing time for more discussion; they should be in the hands of the programme committee by Dec. 1st, 1914. All business communications as to exhibits and all inquiries should be addressed in the first instance to Dr. Arthur F. Cole, Ningpo, China.

WE learn from our New York *correspondent* that Dr. Theodore Janeway, of New York, has been appointed full-time professor of medicine in the Johns Hopkins University, Baltimore. We believe that this is the first appointment of a full-time professorship of medicine which has been made in any English-speaking country, and in view of the report of the Royal Commission on University Education in London the matter is of more than ordinary interest to the medical profession of this country.

THE next session of the General Medical Council will begin on Tuesday, May 26th, when the President, Sir Donald MacAlister, K.C.B., will take the chair at 2 P.M.

Lord Lamington has consented to become President of the Research Defence Society, in succession to the late Sir David Gill.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the thirty-third meeting of the Royal Commission on Venereal Diseases evidence was given by Sir Herbert Smalley, M.D., one of H.M. Commissioners of Prisons.

Sir Herbert Smalley stated that it was his firm impression, and also that of many of the senior medical officers of prisons, that venereal diseases were not so prevalent in prisons as was the case 30 years, and even 20 years, ago, and that, apart from the actual number suffering, the cases were now less severe in character than formerly. He was, however, inclined to think that the later stages of syphilis affecting the circulatory and nervous systems and the so-called parasyphilitic affections were more prevalent. Returns which had been obtained for the five months ending last March showed that rather under 2 per cent. of prisoners received into local prisons presented manifest symptoms of either gonorrhœa or syphilis. An analysis of the figures showed that the highest incidence occurred amongst prisoners committed from large towns, manufacturing or mining districts, and it was also observed that cases of venereal disease were disproportionately numerous in prisons receiving prisoners from seaport towns. He described the methods and precautions adopted with regard to cases of venereal diseases in prisons, and stated that the conditions existing seemed to warrant the assertion that the danger of infection from venereal disease in prison was practically *nil;* he had never known a single instance of such a case occurring.

Sir Herbert Smalley stated that the results of his recent inquiry indicated that about half of those received into prisons suffering from venereal disease were still in an infectious condition when discharged. This problem might be attacked either by detention, notification, or by the provision of facilities for treatment subsequent to discharge. The first alternative, he considered, was of doubtful expediency, and he was of opinion that any form of notification other than that which was made applicable to the whole community would be inadvisable. The idea of a prisoner being specially penalised or of his sentence being enhanced on account of venereal disease would, he thought, be strenuously resisted. He was not in favour of venereal disease being made notifiable generally throughout the community. The provision of facilities for treatment seemed to Sir Herbert Smalley to offer a more hopeful solution of the difficulty. It was necessary, he thought, that means should be provided throughout the country for treatment of venereal disease free of cost, readily accessible, and with attendance permissible in the evening so as not to interfere with the daily work of the patient. As far as possible these centres should be at general hospitals and dispensaries rather than at special hospitals or centres solely for the treatment of venereal diseases. If such centres were organised it would enable a prison doctor to give a discharged prisoner a ticket, the presentation of which at a centre would secure the patient a continuance of treatment. The fact of the patient being recently discharged from prison should be a confidential matter and should be made known at the treatment centre to as few persons as possible. With regard to convict prisons Sir Herbert Smalley stated that the results of some investigations he had made showed that out of 1755 male convicts in certain prisons 299, or 17 per cent., showed signs of having had syphilis. Of 941 inmates examined at Borstal Institution 153, or 16 per cent., gave evidence of congenital syphilis.

London School of Clinical Medicine: Instruction in Venereal Diseases.—A four weeks' course of instruction in the diagnosis and treatment of venereal diseases will be given at the London School of Clinical Medicine, Dreadnought Hospital, Greenwich, beginning on Monday, May 25th. The course is primarily intended to meet the requirements of medical officers in the Colonial Service, but is also open to other medical graduates. There are in the hospital 23 beds maintained for patients suffering from venereal disease.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8938 births and 4896 deaths were registered during the week ended Saturday, May 9th. The annual rate of mortality in these towns, which had been 14·9, 15·1, and 14·2 per 1000 in the three preceding weeks, further declined to 14·1 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 14·7, against 13·8 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 4·9 in Aberdare, 6·2 in Walthamstow, 6·3 in Ilford, 6·4 in Hornsey, and 7·0 in Tottenham, to 19·8 in Ipswich, 20·2 in West Hartlepool, 20·6 in Middlesbrough and in South Shields, 21·8 in Southport, and 22·9 in Bury.

The 4896 deaths from all causes were 42 fewer than the number in the previous week, and included 436 which were referred to the principal epidemic diseases, against numbers rising from 433 to 453 in the four preceding weeks. Of these 436 deaths, 146 resulted from measles, 146 from whooping-cough, 59 from infantile diarrhœal diseases, 44 from diphtheria, 27 from scarlet fever, 13 from enteric fever, and 1 from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3 per 1000, and coincided with that recorded in each of the three preceding weeks. The deaths attributed to measles, which had been 153, 140, and 155 in the three preceding weeks, fell to 146 last week, and caused the highest annual death-rates of 1·3 in Manchester and in Preston, 1·4 in Sheffield, 1·6 in Middlesbrough, 2·1 in Nottingham, and 4·4 in Stockton-on-Tees. The deaths referred to whooping-cough, which had been 117, 166, and 139 in the three preceding weeks, rose to 146 last week; the highest death-rates from this cause were 1·3 in Gateshead and in Swansea, 1·4 in Sunderland, 1·6 in Middlesbrough, 1·7 in Rochdale, and 2·0 in Carlisle. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 61, 66, and 59 in the three preceding weeks, were again 59 last week; of this number 12 were recorded in London, 4 in Liverpool, and 3 each in Birkenhead, Sheffield, and Middlesbrough. The deaths attributed to diphtheria, which had been 50, 40, and 50 in the three preceding weeks, declined to 44 last week, and included 13 in London, 4 in Birmingham, 3 in Bolton, and 2 each in Wolverhampton, Manchester, and Sheffield. The deaths referred to scarlet fever, which had been 40, 23, and 35 in the three preceding weeks, fell to 27 last week, of which 6 occurred in London, 5 in Birmingham, 3 in Manchester, and 2 each in Liverpool, Oldham, Sheffield, and Middlesbrough. The fatal cases of enteric fever, which had been 17, 10, and 15 in the three preceding weeks, fell to 13 last week, and included 3 in Manchester, 2 in London, and 2 in Wakefield. The death from small-pox belonged to Dewsbury.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had declined from 3182 to 2876 in the five preceding weeks, had increased to 2901 on Saturday last; 398 new cases were admitted during the week, against 289, 305, and 377 in the three preceding weeks. These hospitals also contained on Saturday last 1126 cases of diphtheria, 344 of whooping-cough, 105 of measles, and 48 of enteric fever, but not one of small-pox. The 1197 deaths from all causes in London were 81 in excess of the number in the previous week, and corresponded to an annual rate of 13·8 per 1000. The deaths referred to diseases of the respiratory system, which had been 263, 258, and 185 in the three preceding weeks, rose to 221 last week, but were 35 below the number registered in the corresponding week of last year.

Of the 4896 deaths from all causes in the 97 towns, 165 resulted from different forms of violence, and 375 were the subject of coroners' inquests, while 1388 occurred in public institutions. The causes of 48, or 1·0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, and in 67 other smaller towns. Of the 48 uncertified causes of death, 10 were registered in Liverpool, 9 in Birmingham, 3 in Southend-on-Sea, and 2 each in Reading, Stoke-on-Trent, St. Helens, Bury, Gateshead, and Swansea.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1250 births and 713 deaths were registered during the week ended Saturday, May 9th. The annual rate of mortality in these towns, which had been 16·0, 16·9, and 15·2 per 1000 in the three preceding weeks, rose to 16·2 per 1000 in the week under review. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 16·2, against a corresponding rate of 14·7 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 7·9 in Ayr, 11·7 in Clydebank, and 12·3 in Perth, to 19·4 in Greenock, 20·0 in Paisley, and 21·8 in Coatbridge.

The 713 deaths from all causes were 44 in excess of the number in the previous week, and included 64 which were referred to the principal epidemic diseases, against 71 and 61 in the two preceding weeks. Of these 64 deaths, 31 resulted from measles, 17 from whooping-cough, 7 from diphtheria, 4 from infantile diarrhœal diseases, 4 from scarlet fever, and 1 enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·5, against 1·3 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 20, 29, and 19 in the three preceding weeks, rose to 31 last week, of which 19 occurred in Glasgow, 4 in Edinburgh, 3 in Hamilton, and 2 in Dundee. The deaths referred to whooping-cough, which had been 11, 9, and 13 in the three preceding weeks, further rose to 17 last week, and included 10 in Glasgow and 3 in Coatbridge. The 7 fatal cases of diphtheria were equal to the average in the four preceding weeks, and comprised 3 in Glasgow, 2 in Aberdeen, and 2 in Kirkcaldy. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 13, 18, and 17 in the three preceding weeks, declined to 4 last week, of which 3 were recorded in Glasgow and 1 in Dundee. The 4 deaths referred to scarlet fever were slightly below the average for the four preceding weeks, and included 2 in Aberdeen. The fatal case of enteric fever was registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 120, 130, and 90 in the three preceding weeks, rose to 116 in the week under notice; and 16 deaths resulted from various forms of violence, against 31 and 28 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 661 births and 431 deaths were registered during the week ended Saturday, May 9th. The annual rate of mortality in these towns, which had been 22·5, 25·3, and 20·6 per 1000 in the three preceding weeks, further declined to 18·6 per 1000 in the week under review. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 21·5 per 1000; in the 97 large English towns the corresponding rate did not exceed 14·7, while in the 16 Scotch towns it was equal to 16·2 per 1000. The annual death-rate last week was equal to 21·7 in Dublin (against 13·8 in London and 15·7 in Glasgow), 15·2 in Belfast, 19·7 in Cork, 12·7 in Londonderry, 19·0 in Limerick, and 26·6 in Waterford, while in the 21 smaller towns the mean rate rose to 19·0 per 1000.

The 431 deaths from all causes were 46 fewer than the number in the previous week, and included 47 which were referred to the principal epidemic diseases, against numbers declining from 75 to 63 in the three preceding weeks. Of these 47 deaths, 30 resulted from measles, 9 from whooping-cough, 3 from diphtheria, 3 from infantile diarrhœal diseases, and 2 from scarlet fever, but not one from enteric fever or small-pox. The mean annual death-rate from these diseases last week was equal to 2·0, against corresponding rates of 1·3 and 1·5 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 42, 37, and 45 in the three preceding weeks, fell to 30 last week, and comprised 29 in Dublin and 1 in Belfast. The deaths referred to whooping-cough, which had been 14, 12, and 9 in the three preceding weeks, were again 9 last week, and included 3 in Cork, 3 in Belfast, and 2 in Dublin. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 10, 7, and 8 in the three preceding weeks, fell to 3 last week, of which 2 were recorded in Waterford and 1 in Dublin. The 3 deaths attributed to diphtheria, comprising 2 in Dublin and 1 in Belfast, were slightly in excess of the average in the four preceding weeks. The 2 fatal cases of scarlet fever occurred in Dublin.

The deaths referred to diseases of the respiratory system, which had been 115, 112, and 87 in the three preceding weeks, further declined to 74 in the week under notice. Of the 431 deaths from all causes, 121, or 28 per cent., occurred in public institutions and 4 resulted from various forms of violence. The causes of 17, or 3·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes did not exceed 1·0 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeons: L. L. Greig to Royal Marine Depôt, Deal; W. Bastian to the *Columbine*, additional, for service at Cromarty; W. R. Harrison to the *Amethyst*; A. H. S. Richardson to the *Topaze*, on completing; H. A. Browning to the *Research*, and G. C. Cross to the *Endeavour*. Surgeons: A. R. Sharrod to the *Hibernia*; H. E. Y. White to the *Commonwealth*; G. B. Scott to the *Cumberland*, on recommissioning; J. S. Elliott, A. J. Tonkinson, and J. R. Haldane to the *Victory*; G. S. Harvey and H. C. A. T. Cannon to the *Vivid*; W. H. Murray, G. H. Hayes, and H. J. Hopps to the *Pembroke*, additional, for disposal; T. J. KilBride to the *Leander*; P. B. Wallis to the *Vernon*, additional, for the *Niger*; J. P. Blockley to the *Triton*; and R. A. Rankine to the *Ganges*, additional, for Shotley Sick Quarters.

In accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Frank Bradshaw has been placed on the Retired List at his own request (dated April 9th, 1914).

ARMY MEDICAL SERVICE.

Major Harold P. W. Barrow, Royal Army Medical Corps, to be a Deputy Assistant Director-General at the War Office, vice Lieutenant-Colonel B. H. Scott (dated May 1st, 1914).

ROYAL ARMY MEDICAL CORPS.

Colonel F. Butt has been selected for appointment as Deputy Assistant Director of Medical Services to the Second London Division. Colonel R. Kirkpatrick, C.M.G., has been appointed Assistant Director of Medical Services to the Presidency Brigade at Calcutta. Colonel H. J. Barratt has taken up duty at Bareilly Cantonment.

Lieutenant-Colonel J. H. Daly has taken up duty in the Belfast District as Senior Medical Officer of the North Irish Coast Defences. Lieutenant-Colonel R. H. Hall has arrived home for duty from Bermuda. Lieutenant-Colonel J. C. Connor has been appointed to the Irish Command. Lieutenant-Colonel W. Turner has been appointed Deputy Assistant Director of Medical Services to the Welsh Division. Lieutenant-Colonel S. Guise-Moores has been transferred to the Colchester District from Aldershot. Lieutenant-Colonel H. C. Thurston, C.M.G., has been appointed to the Aldershot Command. Lieutenant-Colonel C. W. H. Whitestone has been appointed to hold charge of the Military Hospital at Hilsea. Lieutenant-Colonel H. I. Pocock has been transferred from Murree to Campbellpore Cantonment. Lieutenant-Colonel H. E. Winter has embarked for India. Lieutenant-Colonel C. Dalton has taken up duty at Aldershot.

Major A. E. Hamerton, D.S.O., has been appointed to the Eastern Command. Major F. E. Gunter has been appointed Assistant Surgeon to the Royal Military College at Camberley. Major J. G. Gill has arrived home for duty from India. Major W. J. Crawford has been appointed to the Southern Command. Major J. M. Cuthbert has been appointed to hold medical charge of the Headquarters Staff and Departments in the Scottish Command. Major E. W. Bliss has been transferred from the Eastern Command to the Scottish Command. Major J. C. B. Statham has been appointed to the London District. Major E. F. L'Estrange has been appointed to the Belfast District. Major J. B. Clarke has been placed under orders for service in North China. Major E. T. Inkson, V.C., has been appointed to the Military Hospital at Exeter. Major D. Lawson has been appointed Senior Medical Officer at Mauritius. Major S. O. Hall has been appointed Specialist in Midwifery and Diseases of Women and Children to the Burma Division. Major G. M. Goldsmith has been appointed to the Dublin District. Major G. J. Houghton has arrived home for duty from the Sierra Leone Protectorate. Major A. G. Thompson has been appointed to the Southern Command. Major M. H. G. Fell has been appointed Deputy Assistant Director of Medical Services to the Aldershot Command.

Captain A. S. Arthur has been appointed to the Military Hospital at Pembroke Dock. Captain H. J. Crossley has taken up duty at the Military Hospital, Meerut Cantonment, as Specialist in Advanced Operative Surgery. Captain E. D. Caddell has been transferred from the Irish to the Eastern Command. Captain S. Field has been appointed to the Irish Command. Captain H. O. M. Beadnell has taken up duty at the Military Hospital, Tidworth. Captain J. B. Hanafin has been appointed Specialist in Electrical Science and Radiography to the Third (Lahore) Division. Captain C. H. Denyer has been appointed to the Southern Command. Captain D. de C. O'Grady has been appointed to the Eastern Command. Captain E. C. Phelan has been appointed to the Belfast District. Captain T. S. Blackwell has joined the Colchester District. Captain F. M. Hewson has been appointed to hold charge of the Followers and Cantonment Hospitals at Karachi

Captain P. A. Lloyd Jones has been appointed Specialist in Ophthalmology to the Military Hospital at Aldershot. Captain J. W. Houston has been appointed Deputy Assistant Director of Medical Services for Sanitation to the First (Peshawar) Division. Captain E. C. Lambkin has taken up duty at Hong-Kong. Captain M. Leckie has joined the Southern Command. Captain R. R. Lewis has been appointed to hold charge of the Military Hospital at Port Lokkoh, West Africa. Captain R. E. Humfrey has been transferred from Ireland to India. Captain W. Mitchell has arrived home from India. Captain E. L. Fyffe has been appointed to hold charge of the Cantonment General Hospital and Followers Hospital at Poona. Captain F. W. W. Dawson has been appointed Specialist in the Prevention of Disease to the Jullundur Brigade and placed in charge of the Bacteriological Research Laboratory at Headquarters. Captain J. G. Bell has taken up duty at the Military Hospital, Singapore. Captain H. H. A. Emerson has been appointed Adjutant to the Royal Army Medical Corps School of Instruction at Leicester. Captain J. R. Foster has been appointed to hold medical charge at Kilbride Camp. Captain C. H. Harold has been appointed to hold charge of the Northern Army Bacteriological Laboratory at Ambala Cantonment. Captain A. C. Elliott has taken up duty in the Eastern Command. Captain B. A. Odlum has been appointed to the Military Hospital at Bloemfontein. Captain W. K. Beaman has joined the Northern Command. Captain D. B. McGrigor has been transferred from the Military Hospital at Ranikhet to Agra Cantonment. Captain F. Casement has arrived home from India. Captain T. H. Scott has been appointed to Bradford.

Lieutenant W. L. Webster has been transferred from the Military Hospital at Limerick to Egypt. Lieutenant J. Hare has taken up duty at Enniskillen, on transfer from the Military Hospital at Belfast. Lieutenant E. A. Strachan has been appointed to the Military Hospital at Lucknow Cantonment. Lieutenant H. F. Panton has embarked for India. Lieutenant P. M. J. Power has been transferred from the Military Hospital at Cosham to Winchester. Lieutenant A. G. Brown has been appointed to the Military Hospital at the Curragh Camp.

INDIAN MEDICAL SERVICE.

Surgeon-General W. B. Bannerman, C.S.I., chief medical officer to the Government of Madras Presidency, has been appointed Honorary Physician to His Majesty the King.

Colonel H. E. Banatvala has been appointed to officiate as Inspector-General of Civil Hospitals in the Central Provinces.

Lieutenant-Colonel J. Jones has joined at Bombay. Lieutenant-Colonel S. Browning-Smith, officiating Sanitary Commissioner to the Government of the Punjab, has been granted 18 months' combined leave of absence home from India. Lieutenant-Colonel C. H. James, C.I.E., has been appointed to officiate as Civil Surgeon at Simla East during the absence on leave of Lieutenant-Colonel H. A. Smith. Lieutenant-Colonel A. C. Younan has taken over medical charge of the 25th Punjabis. Lieutenant-Colonel E. Hasell-Wright has been appointed District Medical and Sanitary Officer and Superintendent of the Medical School at Tanjore.

Major J. W. F. Rait has taken over charge of the jail at Hooghly from Captain A. H. Proctor. Major E. E. Waters has been appointed to officiate as Superintendent of the jail at Howrah, vice Lieutenant-Colonel A. H. Nott. Major T. A. Grainger has been selected for advancement to the rank of Brevet Lieutenant-Colonel. Major H. M. MacKenzie has been appointed to officiate as Professor of Pathology at the Government Medical College, Lahore, vice Major W. H. C. Forster. Major H. Innes has arrived home on leave of absence. Major E. C. MacLeod has been appointed to officiate as Inspector-General of Civil Hospitals and Prisons to the Government of Assam. Major W. Selby, D.S.O., has been appointed Professor of Surgery to the King George Medical College at Lucknow. Major W. D. Hayward has been appointed to officiate as Medical Storekeeper at Madras. Major R. H. Price has taken up duty at Kohat.

Captain C. L. Dunn, Deputy Sanitary Commissioner in the United Provinces of Agra and Oudh, has been granted eight months' leave of absence home from India on medical certificate. Captain H. P. Cook has been appointed for special duty in connexion with plague prevention at Fyzabad. Captain C. H. Cross has been appointed for a course of training in the Chemical Examiner's Laboratory in Madras. Captain G. McGregor-Millar has been appointed to hold substantive medical charge of the 55th Sikhs. Captain F. Salisbury has joined at Dacca. Captain J. F. Boyd has been appointed Plague Medical Officer at Ballia on transfer from Bareilly. Captain J. F. James has been appointed to officiate as Civil Surgeon at Sibsagar, Assam. Captain H. H. Thorburn has been appointed to officiate as Civil Surgeon at Meshed and Assistant to the Consul-General at Kerman. Captain A. M. Dukes has been appointed Deputy Sanitary Commissioner to the Burdwan and Presidency Circles in Bengal. Captain T. C. Boyd has taken up duty as Agency Surgeon at Deoli.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Henry Robins Borcherds resigns his commission (dated May 13th, 1914). Lieutenant George E. Pepper is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Northumbrian Field Ambulance, Royal Army Medical Corps: Captain Arthur G. Dunn resigns his commission (dated May 13th, 1914).

2nd Scottish General Hospital, Royal Army Medical Corps: Major Francis M. Caird to be Lieutenant-Colonel (dated April 9th, 1914). Major John D. Comrie, from the permanent *personnel*, to be Major, whose services will be available on mobilisation (dated April 9th, 1914). Captain David James Graham, from the 3rd Lowland Field Ambulance, Royal Army Medical Corps, to be Captain (Registrar) (dated April 9th, 1914).

For Attachment to Units other than Medical Units.—Robert Ellis (late Cadet, Cambridge University Volunteer Rifle Corps) to be Lieutenant (dated May 9th, 1914).

Attached to Units other than Medical Units.—Matthew B. Ray (late Captain, 5th Battalion, The Prince of Wales's Own (West Yorkshire Regiment)) to be Captain (to be supernumerary) (dated May 9th, 1914). Lieutenant Stanley F. Linton to be Captain (dated August 9th, 1913).

Officers Training Corps.—University of London Contingent, Senior Division, Officers Training Corps: Major Wilmot P. Herringham, 1st London (City of London) General Hospital, Royal Army Medical Corps, serving with the University of London Contingent, Senior Division, Officers Training Corps, is appointed to command the medical unit of that contingent, and is granted the local rank of Lieutenant-Colonel (with the pay and allowances of that rank) whilst so employed (dated April 3rd, 1914).

INDIAN MEDICAL SERVICE DINNER.

The annual dinner of the Indian Medical Service, as already announced in THE LANCET, will be held at the Hotel Cecil on Monday, June 8th. Surgeon-General J. H. Benson will preside. Officers desirous of being present who have not already intimated their intention should do so without delay to the joint honorary secretary, Lieutenant-Colonel J. J. Pratt, 63, Addison-road, Kensington, W.

ROYAL ARMY MEDICAL COLLEGE JUNIOR EXAMINATION.

At the recent examination for the junior course of instruction at the Royal Army Medical College Lieutenant A. Watson was awarded the Herbert, De Chaumont, Tulloch Memorial, and second Montefiore prizes, and Lieutenant N. V. Lothian the Parkes Memorial and Marshall Webb prizes.

DONATIONS AND BEQUESTS.—The late Mr. Samuel Massey, of Manchester, whose property amounts to about £6948, has left the residue, after payment of a few small gifts, to the Manchester Royal Infirmary, the Manchester Eye Hospital, the Manchester Hospital for Diseases of the Throat and Chest, and a certain sum is left for other charitable purposes.—By will the late Dr. Charles Bruce, LL.D., of Edinburgh, left £1000 each to the Royal Infirmary, Edinburgh, and the Royal Edinburgh Hospital for Incurables, £750 each to the Edinburgh Institution for the Deaf and Dumb, and the Royal Society for Home Relief for Incurables, Edinburgh. Subject to certain life interests he left the following further bequests: £2500 to the Edinburgh Royal Infirmary and £2500 to the Royal Edinburgh Hospital for Incurables.—By will the late Mr. Thomas Edwin Crocker left £500 each to the Tavistock (Devon) Cottage Hospital, King's College Hospital, the Wimbledon Cottage Hospital, and the Nelson Hospital, Merton.—The late Miss Eleanor Theakston Sprunt, of Emsworth, Hants, has left estate of which £24,853 is net personalty. After bequests amounting to about £1500, the testatrix left the residue of her estate in equal shares to the Royal Albert Asylum, Bagshot; Dr. Barnardo's Homes; the Orphan Working School, Haverstock Hill, N.W.; the British Home for Incurables, Clapham-rise, S.W.; the West Sussex, East Hants, and Chichester Infirmary; the Royal National Lifeboat Institution; the Emsworth Cottage Hospital; the Cancer Hospital, Brompton; and the National Hospital for the Paralysed and Epileptic.—The governors of the Durham County Hospital have received a gift of £1000 from the Ven. Archdeacon Watkins, of Durham, towards the operating theatre.—The late Mr. Roch Raymond Mege left by will £200 to the French Hospital, Shaftesbury-avenue.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 1211.)

XLV.—SOUTHEND-ON-SEA.

IN the course of my peregrinations over England I had by the end of March worked across the metropolis to the border of Essex, and my start for a brief tour in the Eastern counties was made at Southend-on-Sea.

In honour of its rapid growth in population and popularity, Southend-on-Sea has just been promoted to the status of a county borough. Though so near to London and so accessible, it is only during recent times that its advantages as a place of residence or a resort have been appreciated in any marked way. In 1866, or but half a century ago, there were 3400 residents at Southend. Even so recently as 1892 the population was only estimated at 12,500. To-day it has reached the imposing total of 82,000.

The railway companies have contributed to bring about this increase, and have so improved the facilities of communication that many families whose earning partner has business in London nevertheless reside at Southend. This means that there are many and good opportunities for private practice. It is not an industrial town, but a pleasure, health, and holiday resort. The particular local and economic conditions so created do not seem to the medical profession suitable to a large increase of contract practice, and doctors were not a little alarmed to find that a National Insurance Act, which on the whole was planned to suit working-class and industrial centres, would be applied to their very different and special locality. Therefore the Insurance Bill inspired sinister forebodings and general mistrust. During the year 1912 the local practitioners gathered together very frequently, and as the critical Christmas in the history of the legislation approached they met every night.

It was my privilege to be received by quite a large number of local practitioners when I went down to Southend recently, and I found many of them still congratulating themselves on having been very unanimous in the view which they took during the most trying periods. That they gave up the struggle with the unanimity which they had shown in combating the scheme cannot be denied; and now it is probable that not only at Southend but throughout the whole county of Essex 90 per cent. of the available practitioners are on the panel. Yet it would be a great mistake to look upon this as a manifestation in favour of the Act. It simply means that the Essex practitioners thought that if they did not yield worse would happen to them.

Early Dislike of the Act.

It would have been easier, as a matter of fact, to resist the Act in Southend than in many other places because the town is especially free from any competing connexion in the surrounding country. Southend is embraced on three sides by broad waters. The insured population could not have crossed this water conveniently to get medical advice in a neighbouring medical area. Previous to April 1st, 1914, when Southend became a county borough, and thus secured an Insurance Committee of its own, the locality was under the Insurance Committee of the county of Essex. The only county borough that then existed was West Ham, and East Ham was applying to be recognised as a county borough. The population of the county of Essex is put down at 1,300,000, and 290,000 of them are insured. There are many districts where the population is so sparse that it is not practicable to give prescriptions to patients, and the actual number of insured persons for whom the panel doctors have to dispense medicine amounts to 54,000. In Southend itself there should be 19,000 persons insured, but on recently adding up the lists of the panel doctors it was found that the payments effected only covered an insured population of from 14,000 to 15,000. As there are 34 practitioners on the Southend panel this means an average of less than 500 persons per list. It will be seen, therefore, that the Southend practitioners are not so dependent for their living on the classes that come under the Insurance Act as is the case in large industrial centres. But like many averages the figures do not represent what actually occurs. In practice some lists are so small that to lose the patients they represent would not much matter, while others, on the contrary, represent the better part of the practitioner's income. The stout resistance set up against the Act remains justified in the eyes of many doctors by subsequent events.

The resistance, here as elsewhere, broke down through the want of organisation. It was impossible to find out what was happening in other parts of the country. What publicity did take place favoured the partisans of the Act, for it consisted, in the main, of an ever-growing list of places that had given in. Such news, on its recurrent appearance, was very discouraging, and there were no means available of testing the feeling of the profession in other places. Then the Southend practitioners sadly felt the need of a proper fund on which they could rely to back up the victims. "Am I to break my word or am I to be ruined?" was a question raised by some of the practitioners who were most involved. It was very difficult to counsel men to hold out when it was obvious they would lose half their practice and were not likely to receive any compensation. Nevertheless the practitioners had at Southend the advantage of having very few medical aid clubs or societies. So they held out after all the other parts of Essex had accepted the Act, but three or four days before the pledge was withdrawn they did surrender, and they all yielded together. Thus to-day no one can say: "I held out and you did not."

The Expenses of the Committees.

What finally brought the resistance to an end, so I was told, was the news given that Mr. Worthington Evans, M.P., had telephoned that it was no use holding out any longer because the Government had parcelled out Essex among a staff of medical men who were ready to establish a sort of State Medical Service for the county. The chairman of the Essex County Insurance Committee having confirmed the news, the Southend practitioners were called together and given this information. Thereupon it was agreed to accept the Act, and this was done unanimously. Therefore the profession is not divided into two camps; but, as I have already said, it would be a great error to conclude that because all have accepted, therefore all approve of the Act. On the contrary, when I found myself in the midst of some 10 or 12 Southend practitioners it soon became apparent that they had many grievances to ventilate. Naturally, I asked if there was a Medical Committee that might deal with at least some of these grievances, but I soon became aware that the Medical Committee was in itself a grievance. The County Medical Committee had to meet in London and to pay for the hire of its own room and the travelling expenses of its own members. The secretary had an enormous amount of work to do, but received nothing for his trouble. A voluntary levy was attempted, but met with a very poor response.

The present proposal is that the expenses of this County Medical Committee, as also those of the Pharmaceutical Committee, are to be paid by a deduction of one halfpenny out of the floating sixpence for each committee, counting, of course, the halfpenny for each person on the lists of the panel doctors, thereby decreasing the claim of the practitioner from this source. To spend thus their own money in carrying out the Act by establishing a Local Medical Committee they had to obtain special permission from the Commissioners, and some soreness is accordingly felt.

No New Story.

As to the results of the Act, some of the Southend practitioners have recognised that under it they are earning more than before; but if the amount of work they have to do is taken into consideration, then they said that they were earning less in proportion. In the old club practice the patients felt reluctant to take the money of others unless there was really something serious the matter. Now no one has such scruples, and the result is that the panel doctors of Southend are so worried by the importunities of those who have nothing much the matter with them, that they can with difficulty find time to examine properly those to whom, if the exact conditions were realised, they should devote much more time. Not only is this injurious to the patients, but it destroys the value of the cards, for the information which they should supply for statistical purposes is not reliable. Yet no one at Southend, I was assured, has more than 900 persons on his list. What, then, would have happened if the Government had put into this town, as it was proposed, only four practitioners to do the work that is divided to-day among 34 practitioners?

One practitioner, in explaining how the Act had somewhat reduced his income, said that most of his patients belonged to a lowly paid class of clerks. They used to pay small fees and were now nearly all insured persons. And they are not the profitable clientèle that they should be in a place as healthy as Southend with a death-rate of about 9 per 1000. Capitation fees should be very profitable, for there is so little sickness. But this extension of contract practice has affected many doctors. The real grievance here, as in so many other places, is the insuring of the employed sons and daughters of wealthy persons. One case related to the son of a large contractor. On his father's wage sheet he appears as earning 35s. a week, but he also receives a bonus of £20 a month. The family doctor refused to treat on insurance terms the son of this contractor, and as a consequence he lost the whole family. If he had accepted he could not have treated the son differently from the rest of the family, yet for the small sum insured persons pay he ought not to expect so much personal attention.

At Southend, I am sorry to report, it was evident to me that contract work in many instances meant inferior work. The panel doctor must not accept anything above the grant as by law established for fear that to do so might bring about a system of preferential treatment, and yet when he knows the substantial position of some of his patients or their children he naturally feels sore. Formerly it was contemplated charging some insured patients ordinary fees, but deducting from their bills the sums accumulated by the annual payments of 7s. Any arrangement of that sort has, however, been declared irregular. "The Act," one Southend practitioner exclaimed, and others approved his observation, "is glorified club practice. No one would come if he had to pay a panel doctor for such treatment." If partly this was a self-condemnatory remark, partly it was a proof that a very big proportion of the population are resorting to panel doctors—a far higher proportion than had been anticipated. Consequently the old club bottle of medicine method was revived. Any amount of medicine was needlessly given, because the patient would complain if he did not get at least one bottle of medicine.

Insured Women at Southend.

Servants are perhaps difficult to keep at Southend, and mistresses fortunate enough to have them are unduly solicitous about their welfare. Anyhow, the mistresses of domestic servants are, I was told by several doctors, constantly telephoning when there was the least thing the matter with their servants. They used to be more careful when they had to pay for medical advice, as to their credit they very usually did. But the practitioner must not resent being thus troubled or else he may lose the servant's mistress, who is a private patient and pays good fees. I should not have thought servants are difficult to get; indeed, there are so many women domestics and charwomen at Southend that several panel doctors were of the opinion that some 40 per cent. of the insured with whom they had to deal were women. The female patients under the Act always take up much more time than the men, and this has proved the case at Southend, where, also in accordance with general experience, their principal complaints are anæmia, gastric trouble, constipation, and rheumatism. These patients go far to prove that it was a great mistake on the part of the promoters of legislation to have calculated the probable amount of sickness on the experience of the Friendly Societies, particularly when these societies had but few women members. As a matter of fact, panel doctors are now treating "arrears of sickness" among their female patients—namely, women who were ill before the Act was passed, but who had never before been either insured or treated. Such neglected people naturally give more trouble than the former members of Friendly Societies, and they are as frequent at Southend as the smiling lass who turns up after a mile walk and begins negotiations by the statement that she is in "an agony of pain." To add to the extra trouble it has been discovered that insured servants are sometimes sent out to describe their mistress's symptoms and get medicine or ointment, not for themselves, but for the family they serve. Others give their medicine to non-insured dependents.

The Temporary Population.

Then there is at Southend the special trouble that applies to holiday resorts—namely, the treatment of strangers who are insured visitors. Last season the green vouchers were in force, but the majority of visitors were so worried by formalities that they gave the matter up as hopeless and found it less trouble to pay the usual fees. During the forthcoming season it is feared the surgeries will be filled with insured strangers just when a little profitable private practice might be obtained. The attending to these strangers must necessitate a separate system of bookkeeping and cause more clerical work than the probable financial result warrants. On the other hand, it is thought that the conversion of Southend into a borough with its own Insurance Committee will improve the situation. A certain hostility was felt by the Essex Insurance Committee against the doctors because they had given trouble and had so stoutly resisted the Act. Now a smaller and purely local Southend committee, drawn from people who are personally acquainted with the doctors, is more likely to be free from any such prejudice. The Commissioners, however, did not view the matter in the same light. They feared there might not be money enough forthcoming to pay for the working expenses of the Local Insurance Committee. It appears they have calculated that unless there are about 50,000 insured persons the receipts will not cover the expenses of an Insurance Committee; and it has been seen that unless strangers are included there is not half that number of insured persons at Southend. However, the die has been cast, and the best must now be made of the situation.

(To be continued.)

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

Insignificant Trifles.

DURING my 14 odd years of motoring I have come in contact occasionally, either personally or in correspondence, with a few unlucky individuals. As far as their automobile experiences went, they seemed to have had the sorrows of Werther, while other owners of similar cars have expressed themselves completely satisfied. Analysis of the cause of many of these troubles leads to the conclusion that the motorist was more often to blame than the car. Looking at the car of a satisfied owner revealed frequently, by inference, the reason of the worries of the dissatisfied motorist. In one the engine was kept clean, the bearings were always adjusted, nuts subject to vibration were kept tightened, lubricators were charged with grease or oil, water joints were not allowed to leak, springs were kept greased, shackle bolts were lubricated and tightened, the sparking plug points were clean and correctly adjusted, and the ends of the valve lifters were separated only by the thickness of a thin visiting card from the stems they had to lift, while the petrol needle valve was true, and there was an absence of the clatter noticeable in the slovenly kept engine. Most of these details are in themselves insignificant, and the attention they need would probably not occupy more than five or ten minutes a day; but the few minutes saved by ignoring their claim to this slight attention are usually followed by a day of reckoning, in which hours may be spent on the roadside and pounds in the repair shop. I trust, however, that these suggestions will not be an excuse for the other type of owner: I mean the over-careful, fussy one, who also exists, and who likes to look at the piston rings once a week, to grind in the valves almost as frequently, and even to attend to the "big ends" at equally short intervals. There is, of course, a happy medium.

The Cost of Repairs.

Disputes regarding accounts for car repairs are best obviated by first obtaining an estimate. Generally speaking, the repairer is not in a position to give an estimate without first dismantling the engine; but most motor engineers will give a price for dismantling and re-erecting, and then, when the engine is taken down, the actual requirements can be ascertained and demonstrated to the owner, and the price and need for each specified. It may be enough if valves are ground in, new valve springs fitted, and big ends taken up, or bearings may require renewing and timing or other gears replacing. These are points for consideration, and can be discussed when the parts are asunder. In some cases relining the bearings with white metal will suffice, whilst in other cases it may be advisable to replace them with new ones. This depends on the amount of wear and the quality of the material originally used. On well-constructed and carefully fitted cars the life of a bearing is longer than on the cheaper and less carefully built ones. In coming to a decision it is well to remember that though loose parts may run, still they cause loss of power, and when once loose they wear rapidly. A little extra trouble spent in the overhaul may postpone the need of a second one for some considerable time, and moreover may obviate an undesirable road stop.

The Object of Lubrication.

In order to obtain efficiency from an engine and from all moving parts any undue friction must be overcome. Lubrication does this by interposing a film of oil, which keeps the surfaces of all moving parts from coming into contact with each other. As these parts move they throw and squeeze out the lubricant. However well the moving parts are made, when examined under the microscope they are seen to be rough, and when two rough parts work on one another they grind each other and thus cause wear. The film of oil interposed prevents this wear. As already remarked, the tendency is to squeeze this film out, therefore to obviate wear the lubricant must be supplied frequently and in small doses. Car owners who bear this in mind will obtain the maximum life from their engine and working parts, with a minimum expense in the matter of upkeep. A point also to bear in mind is the quality of the lubricant. Though cheap oils may not always be considered the most satisfactory, if made by a good firm they frequently answer as well as the more expensive ones. It is better to buy the oil in bulk, by which method the price is greatly reduced. If when ordering the make of engine is mentioned, the manufacturer will see that a suitable oil is supplied.

A Novelty in Change Speed Apparatus.

When an internal combustion engine is used for the propulsion of a vehicle change speed gears are a necessary evil, and a part of the evil has been the quadrant or gate on the driver's right, which usually interferes with easy access to the seats of the car from that side. A recent American innovation is the electric gear change apparatus, in which the external actuating levers are replaced by an electric device worked from the steering column. In the place of the gate or quadrant there are merely some four or five push buttons. A solenoid—that is, a hollow magnet surrounded with insulated wire—is fitted, and when the button is pushed and the electric circuit is completed by depressing the clutch pedal an electric current circulates through the solenoid, which then becomes a powerful magnet drawing in a rod, and thereby bringing the gear into mesh. All the driver has to do when desiring to change speed is to press the appropriate button. Nothing then happens, however, until the circuit is completed by taking the clutch out. Then the magnet so formed draws the gear into mesh. I understand that the consumption of electric current is small and that this method has been found to answer exceedingly well in America, where it is now largely used. Of course, there is a danger of short circuits, but if this method is well designed and constructed they are not likely to occur.

The Causes of Over-heating.

Over-heating may be due to one of the following causes:—(1) Insufficient lift to the exhaust valve; (2) backward pressure from a choked or partly choked silencer; (3) too rich a mixture; (4) too late an ignition; and (5) some block in the water circulation. A diagnosis is easily arrived at by a process of exclusion. Examine the valve-lifters at work and note if there is too much clearance between the lifter and the valve stem. The thickness of a thin visiting card should be an ample gap. If there is too much clearance the valves will lift late and the exhaust gases will not be thoroughly cleared out by the time the piston descends for the induction stroke. With the engine accelerated note if there is an emission of hot gases from the silencer. If the engine is over lubricated this will be visible; if not, the silencer should be taken down and cleaned. If there is an adjustment on the carburetter so that more air can be admitted, the experiment may be tried of running the engine with an increase in the quantity of air to ascertain if this effects an improvement. The platinum points of the magneto should be examined to see if they are worn, and also if they separate at the right time. A gauge is given with most magnetos showing the correct distance between the platinum points. It is also important that the points should be perfectly true with one another, and if they are worn they should be filed and adjusted. Finally, the water circulating pump should be examined to see if it is working and that the pipes are free. It is a good plan at all times to fill the radiator with distilled water. Ordinary water contains lime-salts, which are apt to deposit, especially in the water-jacket, whence the deposit is difficult to remove.

Carbon Deposit and its Removal.

Carbonisation in motor engines is caused by the products of combustion and the burning of lubrication oil that has worked its way past the piston rings. It occurs in all engines, although with the careful adjustment of the carburetter and the use in correct quantities of first-class lubrication oil, an engine with ordinary work should not deposit carbon under, say, 5000 miles. Carbonisation means impaired efficiency, loss of power and speed, and (what may cause trouble) pre-ignition, which latter is the result of the deposit becoming incandescent from the heat of the explosions, and thus firing the mixture before it is compressed. Until recently the only method was to remove the cylinder covers and "curette" them. This was a satisfactory, although with modern four cylinders cast *en bloc*, rather a troublesome procedure, taking a fairly efficient driver-owner some three to four hours. It is to these that the "Cylclean" process will appeal. Mention of it has previously been made in these notes, but as several inquiries have been received as to the efficiency of this process, I visited the chief depôt of the Internal Combustion Engine Cleaning Company, Limited, and personally saw some half a dozen different engines cleaned. The method is simplicity itself. The sparking plugs, valve caps, &c., are removed. With the exhaust valves on their seats, a pilot gas jet is applied to the carbon. Then a stream of oxygen is directed on to it, which thus completely consumes the carbon and expels it. As soon as sparks cease to fly out the engine will be found to be clean. The flame is applied all round the combustion head, piston top, and valve pockets. The process does not in any way affect the metal in the cylinders, it is speedy and inexpensive, and is undoubtedly efficient. I understand that the company has 500 licensees in the United Kingdom, which means practically that there is one to be found in nearly every district. One correspondent asks whether he could oxygen-clean his cylinders himself, and there is no doubt that with a tube of oxygen and a bit of flexible copper piping it could be done, but personally I think I should prefer to have it done with the company's apparatus and by one of their licensees.

Rattling Glass Screens.

The glass in a screen is usually put in its frame with a strip of rubber under and around so as to prevent any movement. In spite of painting and varnishing the rubber is apt to wear and perish, thus causing an unpleasant rattle. To remove the glass and reinsert a fresh strip of rubber is rather a difficult proceeding. An efficient substitute is to make some papier-mâché out of brown paper and hot water and then to push this pulpy mixture between the glass and the frame all the way round, in much the same way as caulking was done on the old timber ships. After it has become thoroughly dry a coat or two of varnish should be applied.

The Legal Status of a Chauffeur.

According to a case that came recently before the county bench at Canterbury a chauffeur is a mechanic and not a domestic or menial servant. This means that he can be dismissed with a week's notice instead of a month's, as is required for the latter. It is difficult to understand how this decision was arrived at, as a chauffeur is engaged about his master's garage and in driving his employer. It is held that a gardener or huntsman, or practically any employee who has to be frequently about his master's person or grounds, is a menial servant. The conclusion would therefore seem to be that a chauffeur ought also to be considered a domestic servant, though such was not the case in the opinion of the bench at Canterbury.

The Swift Two-Cylinder Cycle Car.

I was recently able to have an interesting trial trip on this 1914 7 h.p. car. It has done well in various test runs, especially in the recent general efficiency trial. The seating arrangements are distinctly good, as one seat is placed behind the other, so as to give more elbow room, and thus to overcome one of the objections to a vehicle of narrow track. The engine is a two-cylinder one, with 75 mm. bore and 110 mm. stroke. The valves are on the near side, cooling is by thermo-syphon, and ignition by a high tension magneto with a variable timing lever close to the driver's seat. Lubrication is by gravity from a tank on the dashboard, to which an auxiliary hand pump is added. Three forward speeds and a reverse, actuated by a gate change, are provided. The transmission is by a cardan shaft universally jointed at each end. The foot brake acts on the cardan shaft, and a hand brake, which is of an expanding type, acts on the rear road wheels. Suspension is by semi-elliptical springs fitted to the front and rear of the frame. The control is by a foot accelerator, with a hand throttle also close to the ignition lever. The car was given a good test, both in traffic and over some 50 miles of Kentish roads and hills. The engine is fairly quiet and the power ample. Petrol consumption is certainly economical—about 35 to 40 miles per gallon. Of course, it is not a four-cylinder, and in traffic it is advisable, when coming to a stop, to drop down to the second speed. Changing of gears on two cylinders is often rather tricky, especially changing down, but I found that after a little practice the lower gear could be slipped home silently with simply a slight double-clutch action so as to spin the lay shaft. With a two-seated body, hood, screen, lamps, and horn—in fact, everything needed except side curtains—the price is £140, and at this it is worth considering by a doctor who is just starting motoring and needs a light and inexpensive car.

The 9 h.p. Morgan Adler Carette.

I recently had the opportunity of a short test run on one of these cars, which are put on the market by Messrs. Morgan and Co., Limited, of 10, Old Bond-street, and 127, Long Acre, London. The engine is a four-cylinder one, with "staggered" exhaust valves, and this arrangement permits of both large inlet and exhaust valves being fitted on the same side and operated by one cam shaft. The carburetter is a Zenith. Though an opening in the undershield is provided for the rare instance of a blocked jet, it would be easier, I think, to remove the whole carburetter, which can easily be done by undoing two nuts and the petrol union. Cooling is by a honeycomb radiator, the water circulating by means of a centrifugal pump. The fly-wheel has vanes on it, and so acts as a fan. Ignition is by a self-timing high tension magneto, which is held in position by a band, and so can be rapidly dismounted should occasion necessitate it. The clutch is of the metal-to-metal cone type. The power is conveyed to the gear-box by means of a shaft with a dog coupling at each end, so that the clutch can easily be removed without taking down the gear-box. Three forward speeds and a reverse are provided, all operated by a gate change lever. The final transmission is by cardan shaft and bevel drive. The foot brake acts on the main shaft, and the hand lever brakes on drums fitted on the rear wheels. Lubrication is by rotary pump, an indicator on the dashboard showing that the pump is operating. The control is by a hand throttle on the steering wheel. During the short test the engine ran very sweetly, and appeared to have an ample reserve of power. The gears were quiet in action and easy to change, and the engine picked up easily in traffic, frequently on the top speed. The clutch, though the car was a new one, was by no means fierce, and took up the drive quite gently. With two up the car easily mounted a well-known town steep gradient. A stop was made half way up the hill, and the car started again quite easily. Of course, the first speed was needed. The brakes were tested on this hill, and both sets were found separately to hold the car in both directions. The springing is satisfactory, and the body, either a tandem or sociable two-seater, is comfortable. The car, complete with hood, wind-screen, and lamps, including head lights, is sold for 200 guineas. My short run on the car enabled me to appreciate fully its swift, quiet, and smooth running which, in my opinion, should commend it to medical men. The only suggestion I would make is that it would be an advantage to have a foot accelerator. Probably, too, it would be an advantage if the shaft between the clutch and the gear box were universally jointed at each end.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

LIVERPOOL.

Retirement of Mr. R. W. Murray.

IT is with much regret I announce the retirement of Mr. R. W. Murray, the senior surgeon at the David Lewis Northern Hospital. Universally regarded as one of the most able and successful surgeons in the city, he will be greatly missed, especially by his colleagues at the Northern Hospital. Mr. Murray has decided to spend some years in travel abroad and in literary pursuits. For many years he has delighted audiences at the Medical Institution by his addresses on surgical subjects, and we look forward to hearing him again when he comes to give us some account of his travels.

Royal Infirmary.

The Lord Mayor will attend in state the morning service in the Royal Infirmary Chapel on Sunday next, May 17th, and afterwards he will visit the wards. The infirmary will be thrown open for inspection, and any medical men who are able to pay it a visit will be very welcome. The Royal Infirmary has been particularly unfortunate this year in the health of its staff. At one time six of the honorary staff were away ill, and in five cases the illnesses were serious, necessitating long periods of enforced idleness. His colleagues are now delighted to welcome back Mr. W. Thelwall Thomas in excellent health, as full of energy as ever, and to see him hard at work again at the Royal Infirmary and the University. They are glad to have Mr. W. Fingland also back with them, though in his case he has felt that a long day of administering anæsthetics was too arduous, and so has had his duties lightened by being appointed consulting anæsthetist to the infirmary. The other invalids are reported to be progressing satisfactorily.

May 12th.

BRISTOL AND WESTERN COUNTIES.

Bristol Insurance Committee.

AT the May meeting of the Bristol Insurance Committee the medical referee's report showed that since last March he had seen 1000 cases, with results as follow: Fit for work, 40·2 per cent.; unfit, 33·3 per cent.; did not attend, 20·9 per cent.; returned to work, 4·3 per cent.; workmen's compensation, 1·3 per cent. In a letter to the committee the Insurance Commissioners said: "The practitioners on the panel are entitled to the whole sum available for the medical treatment and attendance of persons who do not receive their medical benefit through institutions or under special arrangements sanctioned by the committee." The Medical Benefit Subcommittee promise recommendations in regard to these unallotted funds at the next meeting. The total number of insured persons in the Bristol area now exceeds 132,000. There are 640 tuberculous persons under treatment. An arrangement for the after-care of the tuberculous has been made with the Civic League.

Anti-Tuberculosis Campaign in Bristol.

The new dispensary to which allusion was made recently in these columns is an adapted dwelling-house. It provides ample waiting and consulting rooms, a dark room for examination of throats, and a small observation ward. There is also a laboratory. One of the picture houses is at present showing a film which represents the various phases of the campaign against tuberculosis. Bristol now possesses the complete machinery for the campaign against tuberculosis, with the exception of a farm colony, which has yet to be provided.

Dental Needs of the Working Classes in Bristol.

The dental surgeons of Bristol are making a courageous attempt to meet the tremendous demand that becomes apparent in every working-class community for dental surgery at low fees. Premises have been opened in East Bristol at which a staff of 20 legally qualified dental surgeons will attend in rotation. In this way continuous attendance will be provided for between 9 A.M. and 7 P.M. (2 P.M. on Saturdays). Every kind of conservative and mechanical treatment will be carried out. A low scale of fees has been drawn up, and patients will be able to ascertain in advance the cost of any services they require. No person having an income of over £160 per annum will be eligible for treatment. In certain cases payment by instalments will be accepted. Books of coupons can be obtained by those who would like to give them to eligible persons, from whom they will be accepted in lieu of fees. Anæsthetics will be given by medical men. A trained nurse will always be on the premises.

Health of Torquay.

The medical officer of health for Torquay, Dr. T. Dunlop, in his annual report for 1913, states that the death-rate was 13·2 per 1000 and the birth-rate 13·6 per 1000. Twenty-one cases of enteric fever were notified, with 2 deaths. Dr. Dunlop remarks that apparently little attention had been paid to notices warning the public of the danger of eating shell-fish from the neighbouring tidal estuaries, as hardly a season passed without a batch of enteric cases which could only be attributed to eating "cockles." 107 cases of diphtheria were reported, and of these 89 were removed to the isolation hospital. 145 notifications of tuberculosis were received, and 43 deaths, including those of 9 visitors, occurred. Fifty-two deaths were due to cancer, an increase of 7 compared with 1912. Dr. Dunlop draws attention to the decrease in vaccination.

Royal Mineral Water Hospital, Bath.

At the annual meeting of the subscribers to the Royal Mineral Water Hospital, Bath, held recently, the medical report showed that during the year the number of patients admitted amounted to 1346, an increase compared with 1912. The financial statement showed that the income was £5397, and there was a deficit of £271.

May 12th.

SCOTLAND.

University of Edinburgh.

THE annual statistical report has just been issued for the academic year 1912–13. It shows that the total number of students was 3352. Out of that total, 3242 matriculated during the winter session, including 556 women, and 110 in the summer session, including 9 women; 1319 students matriculated in the Faculty of Medicine, 6 being women. The number of members of the general council was 11,941. There were 241 degrees granted to men and 13 to women in the Faculty of Medicine.

George Alexander Gibson Memorial Lecture in Edinburgh.

The first lecture was delivered on May 8th in the Hall of the Royal College of Physicians. Dr. James Mackenzie took as his subject "Dr. George Alexander Gibson: an Appreciation of the Man and His Work." There was a large attendance of Fellows of the College and other members of the profession.

The National Insurance Act and the Edinburgh Royal Maternity Hospital.

The sixty-ninth annual meeting of the board of managers of this charity was held recently. The report showed that there was a considerable reduction in the number of patients, both internal and external. The total number was 1484. It was stated that in 1913 the ordinary income had fallen short of the ordinary expenditure by £300. There was thus a drop of 22 per cent. in the number of cases treated, which necessarily caused difficulty in the training of both doctors and nurses. Up to the present no remedy has been suggested to meet this need, which is felt to the same degree by all similar institutions.

Commemoration Day at Glasgow University.

Commemoration Day will be observed at the University of Glasgow on Tuesday, June 23rd. The proceedings will begin in the morning at 10.30, when divine service will be held in the Bute Hall. Afterwards an oration on Lord Lister will be delivered by Sir Hector C. Cameron. This will be followed by the conferring of the honorary degrees of D.D. and LL.D. In the evening at 7 o'clock a dinner will take place in the University buildings. The honorary graduates will be entertained as guests, and the company will also include graduates and friends of the University, including ladies.

Memorial to the late Miss Janet Galloway.

In the Bute Hall of the University of Glasgow last week a window in memory of the late Miss Janet Galloway, LL.D., a pioneer in the movement for the higher education of women, was unveiled. At the ceremony, which was largely attended, Mr. David Murray, LL.D, gave an appreciation of Miss Galloway's life and work. He described how in 1867 the first University lectures to women were delivered in Edinburgh, and next year a similar course was given in Glasgow. In 1876 there was formed the Glasgow Association for the Higher Education of Women. The University did everything in its power to further the objects of the association, and annual courses of lectures to women on university subjects were given by university professors in university class-rooms. In 1883 the association was incorporated and named Queen Margaret College, and an endowment of upwards of £25,000 was obtained. Next year the college commenced operations in its new home at North Park House, with Miss Galloway as its resident head, and in 1893 what had been dimly foreshadowed in 1868 was accomplished when control of the undertaking was transferred to the university authorities. The task of organising and carrying on the work lay with Miss Galloway, and when the college was incorporated with the university she continued as honorary secretary. In a sense it may be said that Queen Margaret College as a separate institution was Miss Galloway's creation. Later she proved herself a broadminded and judicious administrator, always in harmony with the University Court and Senate, and scrupulous in carrying out their wishes. Principal Sir Donald Macalister, in accepting the window on behalf of the University Court, paid a high tribute to Miss Galloway's work and influence.

Appointment of Assistant Tuberculosis Medical Officer in Dundee.

Dr. John Henderson Hunter, of Dundee, has been appointed assistant tuberculosis medical officer in that city at a salary of £300 per annum. Dr. Hunter, who is a D.P.H. of St. Andrews, was house surgeon and physician in Dundee Royal Infirmary, and afterwards engaged in general practice. In October, 1911, he was appointed assistant to the professor of pathology and bacteriology in the University of St. Andrews.

Montrose Royal Asylum.

At the monthly meeting of the managers of the Montrose Royal Asylum held on May 6th Dr. J. G. Havelock, physician superintendent to that institution, intimated that he would not seek re-election at the annual meeting in June. He had served the board for 25 years, and was severing his connexion with them with reluctance and regret. Dr. V. Stone, who presided, said that Dr. Havelock's term of office at the asylum had been a most successful and effective one, and assured him that the board's regret at parting with him was equal to Dr. Havelock's regret at parting with them.

Lack of Midwives in the Scottish Islands.

At the annual meeting of the Rural Midwives Association, held recently, the Marchioness of Tullibardine, who presided, gave her experiences while acting as a member of the committee formed to investigate the needs of the Highlands and Islands of Scotland in this respect. In South Uist she was told by the medical officer that there was not one qualified nurse on the island. In a neighbouring island there was only one woman, over 80 years of age. She came across another district where no doctor had seen a confinement case for years. In one case all the people were Roman Catholics, and the priest frequently found himself called upon to assist at these cases, with the occasional assistance of the schoolmaster. They had a midwifery text-book in their possession.

The late Dr. James Hunter.

I regret to record the death on April 21st of Dr. James Hunter, late of Dreghorn, Ayrshire. Dr. Hunter had been in failing health for some time, and having retired from practice he went to reside in Edinburgh. He was born in 1843 in the parish of Girvan, Ayrshire, received his early education in Girvan, and afterwards at Ayr Academy. He entered the University of Glasgow and took the degree of M.B., C.M.; he had also the degree of L.R.C.S. Edin. In 1864 he obtained the degree of M.D., with commendation. He went as assistant to the late Dr. Hamilton, of Dalry, where he remained for four years. In 1868 Dr. Hunter was appointed medical officer of health of the parish of Dreghorn, and in addition to the colliery works in the district he had a large private practice. He was an unselfish and indefatigable worker in the interests of his patients, and was much beloved by all. He was in practice for 40 years, and on retirement received a public testimonial. His wife and he spent last winter in the south of England, which improved his health considerably. After returning home he had an attack of broncho-pneumonia, which terminated fatally. The funeral was attended by a large number of personal friends. Dr. Hunter lived an honourable and useful life, and will long be remembered by all who knew him.

May 12th.

IRELAND.

Medical Inspection of School Children.

A PUBLIC meeting, convened by the Irish Women's Reform League, was held last week in the Mansion House, Dublin, to demand that medical inspection of school children should be carried out in Ireland as in England, and that dental clinics should be established in Ireland. It has always been a puzzle why legislation such as that establishing medical inspection of school children should not have been applied to Ireland. Public opinion is now, however, demanding such extension.

The Coming Elections at the Royal College of Surgeons.

The election of President, Vice-President, and Council of the Royal College of Surgeons will take place early next month. The present Vice-President, Mr. F. Conway Dwyer, will without opposition succeed as President to Mr. R. D. Purefoy, whose term of office, to the regret of everyone, now comes to an end. Chief interest, as usual, centres about the election of Vice-President. There are two candidates, Mr. Edward H. Taylor and Mr. William Taylor. The former is surgeon to Sir Patrick Dun's Hospital and professor of surgery in Trinity College, and the latter is surgeon to the Meath Hospital. Both have strong claims, and either would make an excellent vice-president and president. Many friends of the College regret that one or other has not postponed his candidature until the next period of election.

Sudden Death of a Medical Man.

The death of Mr. R. P. Condon, of Newcastle West, occurred very suddenly last Monday. He was travelling to Dublin to seek medical advice, and when in the train became very ill. He died in the railway carriage while in Limerick Station. Mr. Condon had been for many years medical officer of the Newcastle West workhouse and dispensary district.

The Water-supply of Londonderry.

Some time ago the corporation of Londonderry sought from the Local Government Board a Provisional Order to promote a temporary stand-by water scheme, which was refused. The corporation then urged the necessity of such a scheme to safeguard the city until a large scheme could be carried out. The Local Government Board replied that this temporary scheme would result only in a limited supply of water of inferior quality, and that to approve it would induce a false feeling of security, and might delay adequate treatment of the larger issues. The board quote the opinions of experts given to the corporation since 1881, and point out that the only response to this series of warnings had been the neglect of the main question of a large and comprehensive scheme of supply from a new source and the promotion of a succession of stopgap schemes. The Local Government Board, unwilling to share responsibility for the attempts to patch up the existing system, and having regard to all the circumstances of the case, the insufficiency of the scheme, and the objections raised at their recent inquiry, again refuse a Provisional Order, and urge the corporation of Londonderry to press forward a final scheme for obtaining an ample and continuous supply of wholesome water. They further say that if waste were checked with scrupulous care and trade supplies—which account for nearly one-fourth of the consumption—were limited rigorously as soon as it appeared desirable to do so, the risk of disaster feared by the corporation would be minimised.

Belfast Tuberculosis Scheme.

There are in Belfast some 6000 tuberculous people, of whom 1000 require institutional and 5000 dispensary and domiciliary treatment. The Belfast corporation, with the approval of the Local Government Board, has appointed a chief medical tuberculosis officer and two assistants, as well as five nurses for dispensary duty and domiciliary visiting. Two dispensaries are ready, but there is delay because negotiations between the corporation and the guardians in reference to the Abbey Sanatorium are still going on and the arrangements with the Belfast Insurance Committee as regards the treatment of the insured consumptives are still unsettled.

Advanced Tuberculosis.

The treatment of advanced pulmonary tuberculosis is rendered difficult by the innate human desire to end one's days at home. It is impossible, on financial grounds, for institutions to be created all over Ireland, but the county and district councils might act on the suggestion of the Local Government Board and utilise some of the present disused fever hospitals, renamed district isolation hospitals. The Derry county council on May 9th passed a resolution to this end.

May 12th.

PARIS.

A Special Medico-legal Course at the Faculty of Medicine.

A FREE course on the relations between medicine and jurisprudence has been authorised at the Faculty of Medicine of Paris, to be given by a barrister, M. Peytel. It consists of the study of those parts of the law that it is to the interest of the medical man to know for his own advantage as well as that of his patients. It deals with those administrative regulations which the practitioner who is called on to make a report in the interests of justice cannot ignore. Recent laws relating to compulsory attendance on the aged, to workmen's compensation, and especially to industrial accidents, have greatly increased the amount of legal knowledge required by the medical man if he is to avoid being entangled in breaches of the law for which he would be held responsible if his patient suffers injury thereby. Medical responsibility is unfortunately being continuously increased nowadays by the courts. This course from the start has met with great support from both students and practitioners.

Accidents following Transfusion.

M. Wallich and M. Levaditi report an interesting observation on the possible dangers attending the transfusion of blood.[1] Hitherto attention has been directed mainly to examining the donor's blood as to freedom from syphilitic and tuberculous infection. M. Wallich is director of an accouchement service, in which the donor in tranfusion is quite commonly the husband. He examined the blood of husband and wife in 17 cases, and in 75 per cent. found that the two bloods when brought into contact gave a very clear agglutination reaction. If transfusion had been performed in these cases it is obvious that there would have been great danger of agglutination occurring in the vessels of the recipient, and thus probably giving rise to embolism or hæmolysis. From this he concludes that it would be wise before performing transfusion to investigate the presence of such agglutination between the blood of the prospective donor and that of the recipient.

Talipes and Paternity.

Recently a young girl brought an affiliation suit against a former lover, which was energetically defended. The girl asserted as evidence of paternity that her child had a club-foot, while the alleged father suffered from the same infirmity. In default of proof that the period of conception coincided exactly with the time of relations between herself and the accused the court disallowed the claim, asserting further that club-foot was not necessarily a hereditary condition, indeed, the testimony of experts went to prove that the malformation was a fortuitous one, the appearance of which in members of the same family was without significance.

Wind Contusions.

Dr. Laurent, who has recently made known some observations on the effects of modern projectiles, has made a communication to the Académie des Sciences on the phenomena known in military surgery as wind contusions. During the wars of the First Empire numerous cases were cited in which soldiers had suffered severe injury, and had even been killed, by the near-by passage of a projectile or by its distant explosion. These cases were for the most part dealt with in treatises on military surgery as legendary. Dr. Laurent, however, observed during the Balkan war, in the campaign in Thrace, many soldiers without any wound who nevertheless showed signs of cerebro-spinal shock of a more or less serious character. These nerve shocks were evidenced by simple concussion, by tingling and twitching, and even by partial paralysis. Graver disturbances induced a cataleptic condition and were even sometimes fatal, yet at necropsy in such cases Dr. Laurent was unable to find any nerve lesion. He thinks that they are due to the vibration of the air produced by the passage of a cannon ball and to the sudden variations of atmospheric pressure impinging on the middle-ear and giving rise to inhibitory phenomena. Dr. Matignon had previously noted similar cases in Manchuria, and it seems that with the increased rapidity of modern projectiles these phenomena become more and more frequent. At any rate, henceforth these injuries can no longer be looked on as legendary, but must be accorded a place in military surgery.

Rat-bite Fever.

Sokodu, or sokishio, is an infection of undetermined character, which is always consequent on the bite of a rat.[3] It has been frequently observed in China and Japan, and of late isolated cases have been noted in Europe—among others by Dr. Horder, Dr. G. S. Middleton, and Dr. J. F. O'Carroll in the United Kingdom, and by M. Frugoni in Italy. A new case has been seen at Auxerre by M. Lagriffe and M. Loup. Although rat-bites are very frequent in France this affection is extremely rare, and it is difficult to explain the conditions of its propagation. Though the rat that gave the bite could easily have been brought to a European port in a ship, the explanation is still difficult in the case of Auxerre, which is 300 kilometres inland. It is, however, in communication with Havre by the river Seine, on which boat traffic is active. The disease is characterised by fever, headache, and lassitude, beginning some weeks, or even some months, after the bite, when the wound has entirely healed. It is accompanied by a characteristic eruption, consisting of hard, raised, red spots, having the appearance of true nodosities of variable size. The disease proceeds by exacerbations at greater or less intervals, and in the Far East is frequently fatal. Hitherto the cases in Europe have presented only a single attack and have generally resulted in cure. But there is ground for fear that, as in the case of other exotic infections imported into western climes by the development of means of communication, acclimatisation may become rapid, so that western pathology will become enriched by still another disease.

Rapid Treatment of Fracture of the Clavicle.

Dr. Couteaud, Médecin en Chef of the Navy, has devised an ingenious method of treating fractures of the clavicle, which allows a cure to be obtained in about eight or ten days without bandages or apparatus, and without leaving any callus. This method, which is already some years old, has been modified by Dr. Couteaud, and has been communicated by him to the Académie de Médecine. It has been so simplified that anyone can apply it. It consists in making the patient lie on a low bed, letting the arm corresponding to the fractured clavicle hang vertically down outside the bed, the forearm being bent and resting horizontally on a cushion on the floor. This is, in fact, only the application of the principle of continuous extension, of which the position of the shoulder allows a remarkable attainment. In this posture the two fragments of the clavicle appose themselves face to face without any necessity for manipulative reduction, and union takes place in a very short time without the formation of inflammatory callus. In comminuted fractures with much displacement of the fragments, formation of detached splinters, and perforation of the skin, suture of the bone may be useful in exceptional cases, but Dr. Couteaud asserts that even then it is not indispensable. For working men he has observed cases in which it sufficed to maintain this posture by night, the arm being retained in position by day with the usual bandages.

BERLIN.

The Modern Treatment of Syphilis: Professor Lesser's Experience.

THE above subject has been discussed during several meetings of the Berlin Medical Society, the introductory address being read by Professor Lesser, head of the department for venereal diseases in the Charité Hospital. He said that there were four discoveries which had had the effect of bringing about a great advance in the treatment of syphilis. These discoveries were (1) the micro-organism of syphilis—namely, the spirochæta, (2) the conveyance of syphilis to animals, (3) the Wassermann reaction, and (4) salvarsan. The discovery of the spirochæta had enabled us to cut short the case by the excision of the chancre before general symptoms had developed and to proceed at once with a combined treatment by means of mercury and salvarsan. When after this proceeding the Wassermann reaction remained negative for two years it might be assumed that the case had been successfully checked. Cases which came under treatment only after the development of general symptoms must be treated by a combination of mercury and salvarsan. Cases with a negative Wassermann reaction might be treated from the beginning with salvarsan; in other cases the use of mercury must be kept up for 10 or 12 days previously to the employment of salvarsan. An energetic course of treatment consisted in the administration of mercury during six weeks and three injections of salvarsan. By this means the Wassermann reaction became negative in 62 per cent. of the cases, whilst in cases treated for four or five weeks only 32 per cent., and of those treated for less than four weeks only 14 per cent., showed a negative reaction. In tertiary syphilis a combined treatment with mercury and salvarsan was indicated, but special attention was necessary in affections of the central nervous system, the liver, and the kidney. In patients suffering from syphilis of a very severe type the effect of treatment with salvarsan was striking and greatly superior to that obtained by any other method. In general paralysis no reliable improvement had been brought about, but in tabes dorsalis some subjective symptoms had been relieved. Professor Lesser said that he gave three or four intravenous injections of salvarsan at intervals of 10 or 14 days, the dose being from 0·3 to 0·4 gramme for men and from 0·2 to 0·3 gramme for women. Undesirable reactions had become more and more rare since a combination of mercury and of salvarsan has been the standard treatment and since the water has been sterilised previously to each injection. The recurrences of symptoms referable to the nervous system which were alleged to be due to the administration of salvarsan were undoubtedly of syphilitic origin, and passed off under antisyphilitic treatment, although their frequency under salvarsan made it very likely that there was some connexion between them and the use of that remedy. Fatal results were undoubtedly sometimes produced by the administration of salvarsan. Neosalvarsan had no advantage as compared with salvarsan except that it might be injected subcutaneously.

---

[3] THE LANCET, March 2nd, 1912, p. [illegible], and Dec. 28th, 1912, p. 1788.

Views of Other Observers.

In the discussion Professor Wechselmann expressed opinions at variance with those of Professor Lesser. He said that he administered salvarsan without mercury in every case of syphilis. The undesirable symptoms which occurred were considered by him to be due to the combination of mercury and arsenic—a combination which interfered with the functions of the kidneys, and in this way hindered the excretion of salvarsan. Death occurring during treatment with salvarsan was caused by syphilitic endophlebitis. Professor Wechselmann claimed that in recent cases of syphilis he was able to secure the recovery of nearly every patient and to produce a negative Wassermann reaction by the administration of salvarsan. He has given as many as 40 injections to a patient without producing any ill effect. In 45,000 injections no case of death had occurred. In the patients treated since 1910, the first year of the salvarsan method, no tertiary symptoms have developed, although these symptoms, according to statistics compiled by Professor Fournier, used to become manifest in the majority of cases within the first four years after infection. Professor Blaschko said that abortive cures with salvarsan were possible when no general symptoms had as yet developed. In tabes dorsalis no permanent recovery but only certain improvements had been observed, such as reappearance of reflexes, disappearance of pain, and a change for the better in the patient's general state. In some cases where salvarsan had proved unavailing a successful result had been obtained by mercury, and this had led to the combined administration of salvarsan and mercury. The treatment must not be based on the result of Wassermann's reaction alone. A definitive judgment as to the utility of salvarsan could not be given until ten years had elapsed. Professor Oppenheimer reported 135 cases of metasyphilitic diseases which had been treated during the past two years with salvarsan. He said that tabes dorsalis and general paralysis must be regarded as occupying a special position notwithstanding the presence of spirochætæ. Of the above cases 20 were syphilitic affections of the brain, of which 8 were successfully treated; in 3 the symptoms became worse, in 9 the effect was negative, and in 4 cases there were recurrences of nervous symptoms which recovered under continued treatment. Of 15 cases of syphilitic affection of the spine 6 recovered, 2 became worse, and in 7 the effect was negative. Of 50 cases of tabes dorsalis there were 10 in which some symptoms were improved, 11 became worse, and in 29 the effect was negative. Of 24 cases of general paralysis there were 15 in which no result was obtained, 6 showed a rapid progress, and in 3 cases a remission was observed. No fatal result occurred among his cases. The majority of the other speakers, who were very numerous, expressed themselves in favour of a combination of salvarsan with mercury.

BUDAPEST.

Prevention of Ophthalmia Neonatorum.

As the measures hitherto employed for the prevention of ophthalmia neonatorum have not been found satisfactory, the Minister of Public Health has issued a circular according to which every midwife is required to apply one drop of a solution of acetate of silver to each eye of every newly-born infant. The circular lays down the following rules:—

1. Midwives shall carry in their bags 20 grammes of a solution of acetate of silver of 1 per cent. strength and a dropper in a special box. 2. At the birth, after the delivery of the head, the midwife shall well wash the child's eyes with clean tepid water and shall dry them each with a separate piece of gauze or linen. If for any reason the washing of the eyes cannot be done immediately after the birth of the head it must be done afterwards before the infant is bathed. 3. Before being used the eye-dropper must be cleansed both inside and out with tepid water. 4. The midwife shall be exempted from this obligation only in the event of the instillation of the solution having been performed by a medical practitioner. ...... 7. Midwives neglecting these rules make themselves liable to fines not exceeding 200 kronen, and to 15 days' imprisonment for a repetition of the offence.

Sale of Ether in Grocers' Shops.

The Chief Board of Health has refused to grant a request made by a deputation of grocers who applied for permission to sell ether. The Board considered, firstly, that grocers' shops are not suitable places for the storage of ether consistently with public safety; and secondly, that the sale of it by grocers would encourage the reprehensible practice of ether-drinking which has been introduced into Hungary by persons who have returned to their native country after emigration to America, where they have acquired the habit. This is so much the case that in a certain Hungarian county where there are hundreds of returned emigrants the practice of ether-drinking is quite common.

Lunacy in Hungary.

According to the published statistics the number of lunatics under detention in the public asylums has been increasing steadily since the year 1890. Last year it was 10,253, and the expenditure of the Government in connexion with these institutions amounted to more than 5,000,000 kronen. About 600 lunatics have been placed under the care of families, and in private sanatoriums for this class of patient there are from 500 to 600 inmates, so that the total number of certified lunatics amounts to about 11,500.

Post-graduate Medical Study in Hungary.

The central committee of the Hungarian Post-graduate Institute has established courses of instruction in 15 towns, particular attention being naturally paid to those which are held in Budapest, the capital of the country. In this city courses of four weeks' duration are held on single subjects, an arrangement by which a special subject may be thoroughly studied. Not only are there no class fees, but country practitioners, particularly those in the service of the State, receive 8*s.* 6*d.* per day towards their expenses and travel free of charge in order to encourage them to take advantage of the instruction. The special subjects of study include occupational diseases, accidents and injuries to workpeople, treatment of incipient tuberculosis, and treatment of incipient insanity.

May 8th.

TRAINING OF THE BLIND.—A Departmental Committee has been appointed by the President of the Local Government Board to consider the present condition of the blind in the United Kingdom and the means available for their industrial or professional training and for their assistance, and to make recommendations in connexion therewith. The chairman is the Right Hon. W. Hayes Fisher, M.P., and the medical members of the committee are Sir Arthur H. Downes, senior medical inspector for Poor-law purposes under the Local Government Board; Mr. H. B. Grimsdale, ophthalmic surgeon to St. George's Hospital; and Sir Thomas J. Stafford, medical commissioner to the Local Government Board of Ireland. Mr. R. B. Cross, of the Local Goverment Board, is secretary to the committee.

CONFERENCE ON INFANT MORTALITY.—The Right Hon. Herbert Samuel, President of the Local Government Board, will give the inaugural address at the National Conference on Infant Mortality, which is to be held at Liverpool on July 2nd and 3rd, under the auspices of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy. Among the subjects for discussion are milk sterilisation, ante-natal hygiene, the teaching of infant hygiene to the elder girls in elementary schools, the scope and functions of schools for mothers, and the special responsibilities of sanitary authorities in regard to infant welfare. A large number of local authorities and voluntary associations for infant welfare have already appointed delegates.

Obituary.

JOHN ABERCROMBIE, M.D. CANTAB., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO CHARING CROSS HOSPITAL.

THE death took place on April 30th at Augill Castle, Brough, Westmorland, of Dr. John Abercrombie, consulting physician to Charing Cross Hospital and to the Foundling Hospital, and formerly assistant physician to the Hospital for Sick Children, Great Ormond-street.

John Abercrombie was born in 1851 at Cheltenham, where his father, Dr. John Abercrombie, was a prominent physician. He came of Scottish stock: his paternal grandfather, John Abercrombie, was one of Wellington's surgeons; his great-grandfather, John Abercrombie, was Provost of Aberdeen. He was educated at Eton and at Cheltenham College, and proceeded to Caius College, Cambridge, afterwards studying medicine at St. Bartholomew's Hospital. He obtained the M.B. degree of his University and the Membership of the Royal College of Physicians of London in 1877, and was appointed house physician to his uncle, the late Dr. Partick Black, then physician to St. Bartholomew's Hospital. In 1880 he proceeded to the M.D. degree, and in the following year was appointed assistant physician to Charing Cross Hospital. In 1890 he was promoted full physician, and resigned from the active staff in 1905, when he was elected consulting physician. In the medical school of Charing Cross Hospital he served as lecturer on forensic medicine from 1882 to 1901, and in the four following years he was lecturer on medicine. In 1886 he was elected to the Fellowship of the Royal College of Physicians of London.

Dr. Abercrombie's period of office on the medical staff of the Hospital for Sick Children extended from 1884 to 1893. From 1890 up to the time of his retirement from practice he was honorary consulting physician to the Foundling Hospital, of which institution he was elected a governor in 1897.

In this extensive field of work Abercrombie steadily gained for himself a high name as a physician, a teacher and a man of culture. In the out-patient rooms and in the wards, more particularly in the children's wards, his practice was followed very regularly by the students, who came to appreciate both the direct instruction that he gave them, and even more the lessons that he taught them by his sound methods of observation, of sifting and weighing evidence, and of reaching a practical conclusion. His manner of teaching was quiet and deliberate, free from all attempt at display of personal distinction, but carrying with it a sense of thoroughness and conviction. On his colleagues at the "consultations" which were in fashion in those days the same impression was made of the peculiar soundness and value of his opinion in difficult cases. In the medical school his lectures on forensic medicine were of a high order, for the subject was one which was congenial to the character of his mind, and on which he wrote a successful text-book, "The Student's Guide to Medical Jurisprudence." And here it may be noted that in later years he became a Justice of the Peace for Westmorland, and but for failing health would have filled the office of High Sheriff of the county.

Looking back at Abercrombie's connexion with the different medical societies, one finds him always more active as an officer than as a simple member. In his quiet way he was more ready to assist in the management than to contribute to the papers and discussions, and his devotion to the duties of treasurer of the Ophthalmological Society and treasurer of the Association of Medical Officers of Schools was highly appreciated. At the Royal College of Physicians he was an examiner in medicine, and his election on the Council was a proof of the respect felt by the Fellows for his judgment and character.

Those of Abercrombie's friends who were most intimate with him in the early part of his career tell us that his excursions into serial medical literature—the work of abstracting, translating, annotating, reviewing, and generally subediting for weekly and monthly journals—were not made exactly *con amore.* He laboured at medical journalism, as so many young physicians have to labour, in order to keep himself abreast with knowledge and make his position in the profession secure. For a short time he was on the staff of the old *Medical Times and Gazette* when Dr. Philpot was editor, that is, after the days of Druitt, Webb, and William Cholmeley. We believe it was under his leadership that the "Dictionary of Practical Medicine" was begun—to be completed by others. The truth is that what time Abercrombie could spare from professional work, which was now coming to him as a consultant, he began to give more and more to the indulgence of his taste for art. He was a musician of no small accomplishments, but first and chiefly a student of sacred art. Guided by a naturally true and carefully cultivated judgment in this direction, and one of a small coterie of amateur enthusiasts, he formed a collection of Italian and Spanish pictures of the fifteenth and sixteenth centuries, both extensive and of rare beauty and value, which included a Murillo and, as he believed, a Leonardo. Apart from his earnest, quiet work in the wards—his other delight—Abercrombie was best seen and understood in his consulting-room, which was to him less a consulting-room than the home of his treasures of art. He would spend hours on end in minute technical study of artists' methods and materials, and more than once he succeeded in discovering original beauties hidden under tasteless "restorations." It was always a pleasure to him to show and discuss with his friends these and other articles of virtu—jewels, miniatures and precious family relics. He was a Freemason, one of the founders and Past Masters of the Chère Reine (Charing Cross Hospital) Lodge.

In 1903 he married Miss Evelyn Graham, "Sister Victoria" of Charing Cross Hospital, daughter of James Aspinall Tobin, of Eastham House, Cheshire, and sister of Mr. A. Aspinall Tobin, K.C., M.P. With her and their two children his life gradually became less public, more given to the delights of his home and its happy attractions. A little later and his friends were not surprised to learn that he had relinquished practice and his valuable professional appointments in London, and taken up a new life in one of the dales of Westmorland, on the Augill stream, near Brough. There, in a quaint castellated old house with oak-panelled rooms and groined ceilings, where his pictures found a fitting resting-place, in his gardens and in his fields as a country squire and a county magistrate, he was entirely happy. And his happiness was of the truly unselfish kind. He and his wife took in hand the social good of Brough, and a large share of their time and interest was given to it. Abercrombie's character was always easy to read by those who were among his colleagues and intimate friends. He loved, cultivated and practised all that is true and fair and beneficent. In his practice in hospital or as a consultant, and in the simple everyday duties which he took upon himself in his retirement, he was the same thoughtful, wise, but modest unpretentious man, deliberate and sound in judgment, and always honest and generous.

The last year or more of his life was a period of failing health and almost constant suffering bravely borne. His funeral well became his life, for his body was carried to the grave on the farm float, drawn by his own horse, and accompanied by a reverent gathering of the many neighbours, rich and poor, to whom he had proved himself a true friend.

THOMAS FREDERICK PEARSE, M.D. BRUX., F.R.C.S. ENG., M.R.C.P. LOND., D.P.H. CAMB.,

LATE HEALTH OFFICER OF CALCUTTA.

A FEW weeks ago we announced with regret the death of Dr. T. F. Pearse, who had been connected with the Calcutta corporation for a considerable period of time and was its health officer for six years.

Thomas Frederick Pearse came of an old Devon family, and was the only son of the late Francis Bryant Pearse, F.R.C.S. Eng. He was born at Haverstock Hill in 1856. Having already made a name as a promising student, he went in 1874 from University College, London, to the Middlesex Hospital with an entrance scholarship. He obtained many prizes in the medical school, including the Broderip scholarship in 1877. After qualifying M.R.C.S. Eng. and L.S.A. in 1878 he obtained the M.D. Brux. degree and was appointed to the resident staff of the Middlesex Hospital as house physician to Dr. William Cayley. In 1875 he became demonstrator of anatomy in the medical school of the hospital, in which office he made a reputation as a hard worker and successful coach. He obtained the M.R.C.P. Lond. in 1887 and the F.R.C.S. Eng. in 1883. Between 1879 and 1896 Dr. Pearse practised successfully in various parts of England. To a sound knowledge of his profession he brought an attractive and sympathetic personality. He was the inventor of several surgical instruments and appliances, and contributed a number of books, papers, and reports to the medical literature of his time, while for some years he was an esteemed Indian correspondent of THE LANCET.

An intimate friend sends the following appreciation: "Much of Pearse's life was spent in India on the Plague Commission and as health officer to Calcutta. Here he brought to bear gifts of a high order, for in six years he reduced the death-rate of the second city of the Empire 6 points per 1000; he further brought about reforms in vital statistics, food purification, and infant hygiene, while he systematised records and returns. In 1906 the corporation of Calcutta presented him with a testimonial in recognition of his valuable services on behalf of the health of that city, and in 1911 he was made honorary surgeon to the St. John Ambulance Brigade in Calcutta, while after the King's visit to India he received the Durbar medal. Pearse was prolific with his pen, while his interest ranged over a large number of subjects. Though extremely versatile he was always modest and unassuming. He was a fluent speaker and gifted lecturer, facile in dialogue and debate. Failing health compelled him to resign his appointment as medical officer of Calcutta, and he left for England in April, 1913. For many months he had suffered from heart trouble, which the Indian climate and an arduous life of public and professional endeavour accentuated. He reached England broken down in health, and a long and painful illness followed, throughout which he was nursed by his wife, an Irish lady, with loving and loyal devotion and care. He passed away on April 14th and was cremated at Golder's Green on April 18th. He gave his life to science and his heart to the relief of suffering, and by his death medicine loses an ornament."

Correspondence.

"Audi alteram partem."

THE BOY SCOUTS MOVEMENT.

To the Editor of THE LANCET.

SIR,—As a member of council of the Boy Scouts I have been requested by the Chief Scout, Sir Robert Baden-Powell, to write to you regarding the appeal he is now making for £250,000 for a permanent endowment fund, the income from which will be spent for the Boy Scouts movement. Companies of Boy Scouts are now being formed all over the world, and everywhere in this country they are to be seen on Saturday afternoons. No one can fail to be struck by their alert, cheery looks as they pass along the roads, by their civility when addressed, or by their willingness to help to the utmost of their power whenever they are asked.

But it is probable that many of those who are familiar with their appearance have never thought that the Boy Scouts is probably the greatest educational movement of modern times. It is not one-sided, it does not cram the boys with book learning, but it draws out the best that is in them. It trains them in body, in mind, and in morals. It trains their bodies by well-directed exercise in the open air. It trains their minds to observe exactly, to think clearly, to decide quickly, and to act promptly, whether in returning a lost child to its parents or stopping a runaway horse. Last, but not least, it trains their morals by establishing a "scout conscience." Everyone knows how much more sensitive a "schoolboy conscience" is to a breach of the traditions of his school than to a breach of the masters' rules, and in the lives of many, perhaps of most people, the opinion of Mrs. Grundy is more potent than the Ten Commandments in deterring them from doing evil and inducing them to do well. The "scout conscience" is as powerful as the schoolboys', and its great virtue is its unselfishness. The scout must not do anything unworthy of a scout however pleasant it might be, he must be ready to obey proper authority, he must think of others as well as of himself, he must be ready to help when needed, and he must do at least one good deed without hope of reward every day of his life. It is easy to see what an influence such a training as this will have on the lives of the coming generation. To-day the bane of the world is selfishness. In the family it leads to discord and causes the children to neglect the wishes and be indifferent to the comfort or necessities of their parents. It causes the parents to neglect their children and leave them to chance or to the State. It leads the employers of labour to be careless of the needs of their employees. It leads the workmen to shut their eyes to everything but their own desires, to disregard the engagements entered into by their own representatives, and to arrange strikes which will bring much suffering to the wives and families of their fellow workmen as well as a maximum of discomfort or even danger to the whole community. It is most disheartening when one asks help for a philanthropic object to be met by the question, "What am I to get out of it?" and to find that when the questioner sees no prospect of personal advantage he promptly refuses his aid.

To this condition of selfishness there are numerous and noble exceptions. Not the least of these is afforded by the medical profession, whose members, brought as they are by their work into daily contact with sickness, sorrow, and death, give freely of their time, skill, strength, and health, and even sacrifice their lives to an extent which only they themselves know. Often they refuse to take the money which their services have well deserved, and out of their hard-earned savings they give for philanthropic objects more than they can well afford. How very different the spirit is, which actuates many who seek their aid, they have, alas! too many opportunities of learning. The same unselfish spirit that animates the medical profession is what the "scout conscience" is trying to instil into the boys of the present time, who will be the men of the future. For this reason the Boy Scouts movement deserves well of the medical profession, but not for this reason only. Although every advance in hygiene tends to lessen sickness and thus diminishes the fees which attendance on the sick would bring to them, medical men have consistently disregarded their own interests and have welcomed and assisted every movement that promised to lessen disease and increase the health and strength of the people. The Boy Scouts movement is doing much for the physique of the rising generation, but there is much more to be done. As the Chief Scout says, in the slums of our great industrial centres thousands of the poor-class boys are never given a chance to start fair in the race for life, though they might become good citizens and valuable assets to the nation were a little trouble taken to help them. This is one of the things the Boy Scouts movement proposes to do as soon as a sufficient income can be assured to provide the necessary organising staff for this purpose as well as for the training of scoutmasters throughout the country. The Chief Scout is making an urgent appeal for £250,000, as I have already mentioned. Boys there are in plenty who are willing to give their time and energies to the work of scouts, but they need training, and there are not enough scoutmasters, and, willing as they are to do their very best, some of them are insufficiently trained themselves.

This appeal of the Chief Scout is certain to find a welcome amongst medical men. As a rule they are not rich themselves, but I feel sure they will give according to their means, and amongst their patients and friends they may find many who are both able and willing to give provided they are assured that the object is good. In his appeal the Chief Scout says that one friend of the movement writes: "I will give £500 if 100 others will do the same." Another writes: "I will give £100 if 1000 others will do likewise." For my own part I will make one of this 1000, and I trust that every medical man throughout the country will not only contribute as much as he can himself but will induce others to do likewise for the sake of the coming generation and the country.

I am, Sir, yours faithfully,
Stratford-place, May 9th, 1914. LAUDER BRUNTON.

"ENCYCLOPÆDIA MEDICA."

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a circular which has been sent round by Messrs. Green, of Edinburgh, calling attention to a work which is in process of publication termed the "Encyclopædia Medica." To this work a number of writers are said to contribute, and I find amongst them my own name, with the description after it, "Master of Rotunda Hospital, and Professor of Midwifery, Dublin." As I in my present position of Master of the Rotunda, or in my former position of Professor of Midwifery, have never had anything to say to the work in question, I think some correction is necessary.

About the year 1898 I was asked to contribute some two or three articles to the "Encyclopædia Medica," and I contributed them. Since that time I have never had an opportunity of correcting what I wrote, nor have I been asked to do so for the edition which is in process of preparation. Consequently I consider that I should be doing wrong in not pointing out that any articles which are attributed to me in the forthcoming edition may or may not represent my opinions at the present time, and that I take no responsibility for them whatsoever.

I am, Sir, yours faithfully,
HENRY JELLETT.
Rotunda Hospital, Dublin, May 5th, 1914.

THE ELECTRICAL TREATMENT OF MILK.

To the Editor of THE LANCET.

SIR,—In the annotation on the above subject in THE LANCET of May 9th you call attention to the fact that no information has been given about cost in my report. The explanation of this is very simple. The report was on the results obtained by a small experimental, and a large scale (also experimental) plant, the whole cost of which was borne by the health committee of the city of Liverpool, to whom the report was issued. There was, therefore, no need to report on the cost to a body which had all the detailed accounts. I would also point out that the actual laboratory workers on the process had a definite object in view—i.e., to produce a plant which would be suitable for dealing with milk supplied from the corporation milk depôts of this city for the use of babies, and which would be more satisfactory than the present steam sterilisation method. For larger supplies a larger plant at an increased cost would be necessary, and there are other factors which would make it very difficult to give an estimate of cost without actual details in each individual case being first obtained.

The report was circulated in order to invite criticism and that workers on this field might know what progress had been made. Our whole conception of the process is that it is a scientific experiment which, if the success already obtained is continued in future work, will prove of practical and economic value in dealing with contaminated milk-supplies; but we deprecate most strongly the introduction of the commercial aspect into the question. We are anxious to give all information and all facilities to anyone working on the scientific side, and would welcome the erection of a similar plant in any other scientific institution; but to municipal authorities or others who wish to use the plant for dealing with their milk-supplies we would say, wait until the process has had at least a year's trial, when its efficiency and its economic possibility will be proved or disproved.

In regard to your remarks about purity at the source of our supplies I most cordially agree, but the condition for which we are all striving, a pure milk-supply, seems still in the far distance, and it would be a fatal policy to reject temporary and even imperfect measures while we are trying to reach the ideal. Liverpool's health committee stands, I think, alone in maintaining at considerable cost its corporation sterilised milk-supply depôts, but this fact has not caused it to relax in any way its efforts to secure a pure milk-supply.

I am, Sir, yours faithfully,
J. M. BEATTIE,
Bacteriologist to the City of Liverpool.
University of Liverpool, May 12th, 1914.

THE CAUSATION OF POST-OPERATIVE MASSIVE COLLAPSE OF THE LUNG.

To the Editor of THE LANCET.

SIR,—The clinical features of post-operative massive, or lobar, collapse of the lung are gradually becoming recognised, and observers appear to be in agreement concerning them, but opinion is still divided as to the cause.

Although my efforts have been chiefly devoted to establishing the clinical characters of the condition, certain features of post-operative collapse and the association of an exactly similar state of the lung with definite paralysis of the essential muscles of respiration have, from the first, led me to believe that the phenomenon is determined by some reflex nervous agency. But I have always been conscious of the difficulty of accounting for it by simple inhibition of action of the diaphragm on the affected side.

The interesting and suggestive article of Dr. T. R. Elliott and Dr. L. A. Dingley in THE LANCET of May 9th makes some important additions to our exact knowledge of massive collapse, for they have found under X rays that the affected lobe is completely collapsed, that the heart is considerably displaced, and the diaphragm immobile on the affected side, thus confirming conclusions which were based on unaided physical examination. Their examination of the various means by which collapse of the lung may be brought about emphasises the difficulties attending the "reflex diaphragm inhibition" hypothesis, which I have tentatively advanced.

After giving reasons for believing that the bronchiole muscles can contract to the point of cutting off the air entry to the alveoli, they reject this explanation on the ground, as I read them, that it is most unlikely that the bronchiole muscles in man would be excited to such a reflex action locally and cause lobar collapse, and, further, that collapse from such a cause would not occur without a preceding phase of asthma. Now this, to my mind, is the most suggestive part of their paper. For although we have still much to learn about the function of the bronchial muscles, there seem to be fewer *a priori* objections to sudden complete reflex spasm of the bronchiole muscles of one lobe as a cause of lobar collapse than there are to the sudden simultaneous occlusion of all the bronchioles of one lobe by viscid secretion, which is the view favoured by Dr. Elliott and Dr. Dingley. The objection on the ground of the absence of an asthmatic phase is not a serious one. As the bronchiole spasm would differ in kind or degree in the two conditions, differences in the type of dyspnœa need occasion no surprise. Against the difficulty of accounting for the limitation of such a reflex to a single lobe the simultaneous interference with the function of the distending muscle of that lobe may conceivably contain the answer. For it must be remembered that experience based on the study of cases of paralysis of the muscles of respiration shows that there is a close correspondence between the area of lung affected and the range of action of the paralysed muscle.

The explanation of acute lobar collapse by simultaneous blocking of all the bronchioles of one lobe (and one lobe only) by viscid secretion appears to me to be open to the following objections. (*a*) The inherent improbability of the limitation of an acute infective process to the whole of the bronchioles of a single lobe, simultaneously. (*b*) The complete absence in several of the recorded cases of any premonitory symptoms suggesting bronchial trouble. (*c*) The appearance—within two or three hours of onset, or even sooner—of greenish, airless, mucopurulent sputum: an order of events quite at variance with the appearances usually presented by the expectoration in the initial stages of acute bronchial inflammations. (*d*) The rapid and complete disappearance of cough and expectoration in uncomplicated cases (*i.e.*, without secondary broncho-pneumonia) after an interval of from 24 to 48 hours. (*e*) The occurrence of well-marked cases of post-operative massive collapse without any cough or expectoration at all. (*f*) Why should a strictly limited lobar bronchitis, such as that postulated, arise only in connexion with a certain kind of operation; and why should this type of bronchitis be especially associated with operations on the appendix and the pelvic viscera? (*g*) The initial pyrexia is not an argument of much weight in favour of acute bronchial infection, as it may be met with in other conditions in which a large tract of lung is suddenly placed out of action—e.g., pulmonary infarction.

If I have laid too much stress on muscular paralysis or inhibition as a factor in causation I think Dr. Elliott and Dr. Dingley have erred in like manner in regard to the viscid secretion. For all that their communication is of very real value, and will, I believe, prove to have taken us forward a step in the elucidation of the cause of post-operative massive collapse. As regards the viscid expectoration I adhere to the belief that its characters and amount depend on the condition of the affected lobe at the moment of collapse; in other words, that it consists of the contents of the lobe, which are expressed from it as it collapses.

I cannot admit, as Dr. Elliott and Dr. Dingley suggest, I fancy out of courtesy to myself, that there can be two mechanisms of post-operative lobar collapse. We are, I believe, both of us wrong at present, but I have an impression that the stone they have rejected and I am disposed to pick up will find a place in the construction of the true theory of massive collapse.

I am, Sir, yours faithfully,

Chandos-street, W., May 11th, 1914. W. PASTEUR.

THE MEDICAL INSURANCE AGENCY.

To the Editor of THE LANCET.

SIR,—I would like to draw the attention of members of the medical profession to the advantages of effecting insurances through the medium of the Medical Insurance Agency.

The agency was started originally with the idea of assisting medical men to arrange their insurances under the Workmen's Compensation Act when that Act came into force in July, 1907. Its scope and usefulness, however, have developed to a large extent, and a great deal of business, notably life and motor-car insurance, is being transacted, and the steadily increasing numbers who insure through the agency show that its efforts are appreciated. The object of the agency is to assist medical men in the choice of an office in which to place their insurances. The business transacted by the agency is not confined to any particular office, but endeavours are made to place insurances to the best possible advantage of the members.

Those taking advantage of the agency not only help themselves but at the same time contribute towards helping deserving medical charities, as, after allowing rebates to insurers and the payment of working expenses, any surplus so remaining is distributed in the above manner. Since its inauguration the agency has refunded to insurers something like £3000, while in addition no less a sum than £800 has been distributed to medical charities.

Full information as to all classes of insurance may be had on application to the Medical Insurance Agency, 429, Strand, London.

I am, Sir, yours faithfully,
G. E. HASLIP,
Chairman of the Committee, Medical Insurance Agency.
London, W.C., May 8th, 1914.

DOMICILIARY TREATMENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I am instructed by the Huntingdonshire Medical Committee to send you a copy of the following resolution which was carried unanimously at its meeting on May 5th.

That in view of the necessity of treating many cases of tuberculosis at their own homes it is absolutely necessary that in a rural area such as this the local medical men should take a share in the treatment.

I am, Sir, yours faithfully,

Huntingdon, May 7th, 1914. J. R. GARROOD.

DIATHERMY IN VESICAL HÆMORRHAGE.

To the Editor of THE LANCET.

SIR,—We have read with much interest Mr. R. H. Jocelyn Swan's excellent paper on Tumours of the Urinary Bladder, published by you last week, particularly with regard to the treatment of hæmaturia in cases of carcinoma where radical operation cannot be carried out, and notice that he makes no reference to "diathermy" treatment. Whatever effect this treatment may have on the growth itself there can be no doubt whatever as to its effect on the hæmorrhage in certain cases, and in our series of four—which we hope to report in due course—we have succeeded in arresting severe hæmorrhage for months. As the treatment can be carried out with no more discomfort to the patient than the introduction of an ordinary catheter passed most gently and with strict aseptic precautions, we think this method of treating vesical hæmorrhage should prove a distinct advance on the methods described by Mr. Swan as being standard ones.

We are, Sir, yours faithfully,
C. E. IREDELL.
RALPH THOMPSON.
Guy's Hospital, May 12th, 1914.

MEDICAL PRACTICE UNDER THE INSURANCE ACT: THE ALLEGATION OF BRIBERY.

To the Editor of THE LANCET.

SIR,—My attention has been called to the remarks which your Special Commissioner recently made on the subject of the bribing of insurance agents, and I shall be glad if any of your readers who can give any further information with regard to this matter would communicate with me so that any possible action may be taken to stop a very unfair and odious practice.—I am, Sir, yours faithfully,

R. M. LEONARD,
Secretary of the Secret Commissions and Bribery Prevention League, Incorporated.
9, Queen-street Place, London, E.C., May 8th, 1914.

THE LATE COLONEL J. O. WILL, R.A.M.C.

To the Editor of THE LANCET.

SIR,—I have to thank you for your great kindness in inserting an appeal from Drs. Blomfield, Dick, and Sichel on my behalf. A very great many have most kindly responded, and I should be much obliged if you would allow me to convey to them through your paper my most grateful thanks. I am trying to write to them personally but have not all their addresses. If you will allow me I should like also to publish in your columns later on a statement of the total amount received. Again thanking you, I am, yours truly,

K. E. WILL.
Brunswick Lodge, Dunton Green, May 12th, 1914.

WILLIAM HAWES AND ALEXANDER JOHNSON.

To the Editor of THE LANCET.

SIR,—It is flattering to an occasional writer to find that a medical historian so erudite as Dr. Raymond Crawfurd should not only read him, but point out his supposed delinquencies. The gist of Dr. Crawfurd's criticism in your issue of May 2nd is that Hawes was a plagiarist and somewhat of an impostor. But is this quite a fair view of the case? William Hawes is allowed the title of M.D. by his biographer in the "Dictionary of National Biography," and is also referred to in the same article as "physician to the London Dispensary." This title of M.D. apparently dates from 1780–81, according to his German biographer (Biogr. Lex., 1884).

That he was a plagiarist is open to grave doubt. According to his biographer in the "Dictionary of National Biography" he derived his ideas from his friend Dr. Cogan's translation from the Dutch of "Memoirs of the Society instituted at Amsterdam in favour of Drowned Persons," 1767–71. This translation was made in 1773 on Thomas Cogan's return from Holland. Hawes probably used Cogan's translation again when writing on the subject of premature burial in the Annual Register (1777).

Alexander Johnson's chief pamphlet, published in 1773, republished under a different title in the same year, is mainly made up of cases "selected from the (Dutch) Society's account of the success of its undertaking." These cases fill nearly the whole pamphlet from p. 11 to p. 138. It is, in fact, little more than a compilation or transcript from the Dutch. The few introductory pages scarcely count, except that with some appearance of spleen they omit the names of Hawes and Cogan from a list of those interested in the recovery of the drowned. Dr. Fothergill's name does appear in the list, and again he figures with Hawes and Cogan in the foundation of the Royal Humane Society. He was apparently in sympathy with both sides and was, moreover, an M.D. (though Cogan was one, too, for the matter of that in 1774).

Spilsbury may have hated Hawes for some private reason, and Johnson may have looked down on Hawes as upon a mere apothecary in 1773. Cogan's translation was probably at the root of the quarrel. Time with its love of shocking revelations may perhaps show that Johnson lifted Cogan's work! Cogan was certainly a good Dutch scholar, and so fond of Holland that he lived there in the great house of the Zulesteins for some years. He certainly worked very hard with Hawes to found the Royal Humane Society. Both surely deserve halos if only for their powers as organisers.—I am, Sir, yours faithfully,

May 7th, 1914. THE WRITER OF THE ANNOTATION.

THE NATIONAL INSURANCE ACT.

SANATORIUM BENEFIT IN MIDDLESEX.

IN Middlesex the county council has signified its willingness to provide treatment for all persons suffering from tuberculosis, whether insured or uninsured. The Insurance Committee, therefore, has entered into an agreement to hand over to the county council all moneys in the sanatorium fund after payment for domiciliary treatment, drugs, medical extras, and administrative expenses. It is estimated, however, that the available balance will by no means suffice to meet the cost to which the county council will be put in respect of tuberculous insured persons, but will, in fact, only maintain 100 out of 250 beds in institutions required for insured persons. As a member of the Insurance Committee put it at a recent meeting, of 250 persons who have paid by their insurance contributions for institutional treatment 150 will be in the position of having to receive treatment at the cost of the rates, the insurance fund being inadequate. Not unnaturally, longing eyes were cast upon the domiciliary 6d. in the hope of making up the deficit, and a proposal was actually made by a member of the committee to reduce the amount set aside for domiciliary treatment and to increase to that extent the contribution towards the expenses of the county council. However, the suggestion was not persisted in and the agreement with the council was ratified. The length of the agreement was fixed at 60 years in order to make it coterminous with the period for which the council has arranged to raise a loan for capital expenditure. Nevertheless the hope was expressed that long before 60 years had elapsed tuberculosis would be as unimportant as some of the zymotic diseases are now. The county council agrees to place 60 beds in sanatoriums and 40 in hospitals at the disposal of the Insurance Committee. On April 29th 155 insured persons were under treatment in institutions and there was a waiting list of 148, which would have been larger but for the fact that, owing to the hopelessness of getting institutional treatment in a reasonable time, patients who should be dealt with in that way were receiving other forms of treatment as a temporary expedient.

BIRMINGHAM INSURANCE COMMITTEE.

The Birmingham Insurance Committee, in adopting the report of their Sanatorium Subcommittee, had laid before them a letter which had been sent to the medical men upon their panel urging the necessity for early application for sanatorium treatment on the part of insured persons suffering from tuberculosis. The letter had been sent in the hope that the medical men would use their influence to induce patients to seek sanatorium treatment at the earliest possible moment. The same committee, in adopting the report of their Medical Service Subcommittee, had before them the case of a medical practitioner who had been previously censured for acting negligently in not properly examining a patient. He was now reported to have informed a patient that if not satisfied he could go and be examined at the tuberculosis institute, and in giving him a prescription to have instructed him to take it to a druggist whom he named. The committee expressed strong disapproval of the practice of sending a patient to a particular druggist, and in recommending censure of the medical man intimated that a more serious view would have been taken if the case had not arisen before their previous censure had been passed upon the practitioner involved. In another case the medical man complained of was reported as having acted negligently in persistently refusing to attend a patient on several occasions, in not providing proper treatment, and in issuing a certificate when he had not seen the patient for seven days. It was recommended that representations should be made to the Commissioners with a view to the removal of this practitioner's name from the panel.

VOLUNTARY HOSPITALS AND THE INSURANCE ACT.

At the dinner of supporters of the Miller General Hospital for South-East London, held under the chairmanship of Sir Edward Coates, M.P., a deficit of £2665 for the past financial year was referred to, and the needs of the hospital for building and other purposes were laid before those present. The chairman described hospitals in general as going through a very serious crisis, due in part, at any rate, to the Insurance Act, which had created an excuse for some people to withdraw their subscriptions. He expressed anxiety lest the voluntary system might be receiving a check, and deprecated the possible superseding of voluntary hospitals by State-aided institutions, describing the words "supported by voluntary contributions" as a national sky-sign of which the people in this country were justly proud.

A LEADING FRIENDLY SOCIETY AND THE INSURANCE ACT.

The Manchester Unity of Oddfellows, which bases its financial returns upon a membership of 771,055, of whom 152,193 are women, does not appear to have serious reason to fear insolvency through any alleged failure of the medical profession to detect malingering or properly to treat disease. For the first nine months under the Act the Manchester Unity paid in sickness benefit to men £196,628, its probable liability having been actuarially estimated at £213,196. With women members it has fared somewhat differently, the estimates for sickness benefit having been exceeded by £6011, the actual payments being £48,303 and the actuarial estimate £42,292. Maternity benefit is not included in the above figures. The society paid to men in respect of this benefit £46,711, the estimate for the same period being £62,350, and to insured women £905, as against £1237. It will be seen that whatever they may have done in the matter of other sickness women have kept well within the expectation formed of them with regard to maternity so far as the Manchester Unity is concerned.

EAST RIDING INSURANCE COMMITTEE.

At a meeting of the East Riding Insurance Committee at Beverley a discussion took place upon an allegation made that some medical men upon the panel were obliging women patients to pay over to them the whole of their maternity benefit for attendance. Protest was made against this, but it was apparently not established that the practice if it existed was in any way general, a member pointing out that Approved Societies generally had maternity cases looked after by a lady who would see that the woman was receiving proper attention. He had never in his experience heard of a medical man "dunning" patients in the manner described. Various opinions were expressed, and it was suggested that publicity having been given to the matter if any medical man were really acting as alleged he would be warned. The matter then dropped. Among other subjects mentioned was the loss of their cheques by three of the medical men on the panel, one being for £47, which the owner knew he had unintentionally thrown into the fire. Fresh cheques were ordered to be drawn.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The Linacre lecture will be delivered on May 25th by Sir T. Clifford Allbutt, Regius professor of physic, on Public Medicine and Hospitals in Ancient Greece and Rome.

The following medical degrees have been conferred:—

M.D.—E. G. Fearnsides, Trinity Hall.
M.B., B.C.—R. Sherman, Caius, and M. T. Petty, Downing.
M.B.—R. S. Morshed, Trinity.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The annual meeting of this association will be held on Monday, May 25th, at 5.30 P.M. (tea and coffee at 5.15 P.M.), at 124, Harley-street, W. The President, Professor G. Sims Woodhead, M.D., will take the chair.

MEDICAL INSPECTORSHIPS UNDER THE BOARD OF CONTROL.—The Secretary of State has approved of Robert Welsh Branthwaite, M.D., Albert Edward Evans, M.B., and Samuel Ernest Gill, M.D., for appointments as inspectors under the Board of Control, the second named to fill the post of Welsh-speaking inspector.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At a meeting of this society at 11, Chandos-street, Cavendish-square, London, W., to-day (Friday, May 15th), at 8.30 P.M., a paper on Some Surgical Aspects of Tropical Diseases will be read by Mr. James Cantlie; Dr. G. C. Low will show a specimen of Dr. A. Castellani's new parasite the "Entoplasma"; and Dr. C. M. Wenyon will show specimens of Oriental Sore in Dogs from Dr. A. R. Neligan, of Teheran.

THE annual banquet of the Coroners Society of England and Wales will be held at the Holborn Restaurant, London, on Thursday, June 18th, at 6.45 for 7 o'clock.

THE annual meeting of the East End Mothers' Lying-in Home will be held at 8, Little College-street, Westminster, S.W., on Wednesday, May 20th, at 4 o'clock.

MUNICIPAL HONOUR FOR A MEDICAL MAN.—At the last meeting of the Cheltenham town council Dr. Richard Davies, a former councillor, was unanimously elected an alderman.

PHARMACEUTICAL SOCIETY.—Dr. Andrew Balfour, director of the Wellcome Bureau of Scientific Research, and Mr. J. R. C. Stephens, medical missionary, Nigeria, have been elected corresponding members of the Pharmaceutical Society.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST: CENTENARY FESTIVAL DINNER.—A dinner to celebrate the hundredth anniversary of the foundation of the Royal Hospital for Diseases of the Chest, City-road, was held at the Savoy Hotel, London, W.C., on Friday, May 8th, Dr. W. H. White in the chair. Those present included Sir Richard Douglas Powell, Sir A. Pearce Gould, Sir StClair Thomson, Professor Sims Woodhead, Dr. Samuel West, Dr. Mitchell Bruce, Dr. Hector G. Mackenzie, Dr. S. H. Habershon, Dr. J. E. Squire, Dr. F. T. Smith, Dr. Glover Lyon, Dr. F. J. Wethered, Dr. R. A. Young, Mr. W. T. Lister, Dr. Arthur Davies, Dr. T. D. Lister, Dr. James Calvert, Dr. J. H. Drysdale, Dr. P. Horton-Smith Hartley, Dr. R. Murray Leslie, and the Dean, Dr. Barty King. After the chairman had proposed the toast of "The King," Sir Richard Douglas Powell, in proposing the toast of "Prosperity to the Hospital," heartily congratulated it on having attained its hundredth birthday, and on having preserved all through that time its vigour and beneficence. He referred to the vast amount of research and useful work which had been carried out in the hospital, and believed that it was destined to a greater usefulness and to spread its fruits over a greater area. He contrasted the treatment of consumptive patients in the Victorian era with that of to-day. He then described a recent visit paid by him to the hospital, and spoke of the great improvements which had been carried out in the out-patient department, referring to the new equipment and installations. He was specially struck with the new department for the prevention of consumption, which would be of the greatest possible value in obtaining accurate and valuable statistical records of the etiology of tuberculosis, and with the electro-cardiograph and other instruments for scientific investigation of heart diseases. Dr. Arthur Davies, in reply, gave a short account of the history of the hospital. It was founded in 1814 by the Duke of Kent, the father of Queen Victoria. It was first situated in Union-street, Bishopsgate, and in 1847 it was removed to Dean-street, Finsbury-square, and in 1849 to its present site. In 1863 it was rebuilt. In 1829 one of the physicians, Dr. Babington, invented the glottiscope, which was the forerunner of the laryngoscope. In 1862 Dr. Thomas Davies, grandfather of the present senior physician, introduced the Laennec stethoscope into England; he also originated the practice of exploratory puncture in the diagnosis of pleural effusions. In 1848 Queen Victoria accepted the office of patron to the hospital, which was henceforth called the Royal Infirmary for Asthma and Consumption. In 1867 the title was changed to that of the Royal Hospital for Diseases of the Chest. Professor Sims Woodhead, in proposing the toast of "The Medical School," referred to the fact that clinical lectures were delivered in the hospital as far back as 1823. The history of the hospital showed that it was staffed in its early years, not only by men of high ideals, but also by strong, practical, and energetic men who were capable of putting those ideals into practice. Dr. Matthew Baillie, nephew of John and William Hunter, who died of consumption in 1823, was one of the first to show the importance "of a careful observation of the dead, in order to discover what had been happening among the living." Nowadays special personal training in the treatment of tuberculous cases was necessary. Professor Woodhead maintained that the medical officer of health could never take the place of the clinician and investigator, and expressed the hope that if laboratories were to be founded and developed these laboratories must be in close connexion with the clinical material, otherwise there was a danger of public laboratories becoming mere centres for the routine collection of statistics. Dr. Barty King, in response, mentioned that two years ago it was decided by the hospital staff to establish a medical school, along with a school for the training of tuberculosis nurses. At its foundation the medical school had to face exceptional difficulties, more especially in connexion with the passing of the National Health Insurance Act; but in spite of these difficulties it had met with an immediate and encouraging success. He referred to the necessity for the training of tuberculosis officers for the tuberculosis departments and sanatoriums, for which there was at present no adequate provision. The general and special hospitals should actively combine in safeguarding their interests in connexion with the new movements, and especially in relation to tuberculosis. The Dean then paid special tribute to the work as carried on at the Brompton Hospital, and also alluded to the high value placed by German physicians on the chest hospitals in London as essential factors in any campaign against tuberculosis. In connexion with the hospital, he mentioned that during the last two years the whole of the out-patient department had been rebuilt, and that tuberculosis and cardiological departments and pathological laboratories had been established and equipped. The council was about to appoint a director of the pathological laboratories in order that, in addition to the ordinary routine work of the hospital, thorough research work might also be carried out. The council had decided to make a special appeal for £60,000 for the endowment of research and the rebuilding of the hospital. Sir Alfred Pearce Gould proposed the health of "The Guests," and Sir StClair Thomson and Dr. Mitchell Bruce replied to the toast; and Dr. Samuel West proposed the toast of "The Chairman," which was replied to by Dr. W. H. White.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 28 cases were considered and grants amounting to £270 voted to 23 of the applicants. The following is a summary of the cases relieved:—

Widow, aged 53, of L.F.P.S. Glasg., who practised at Winchcombe and Bilbao. Since husband's death has tried to earn a living by taking in boarders, but owing to heavy expenses in connexion with the illness of son, recently deceased, and dearth of boarders is in arrears with rent. Granted £10.—Widow, aged 54, of L.R.C.P. Edin., who practised at Blackburn. Since husband's death has been able to earn a few shillings weekly by nursing. One daughter learning a trade. Recently suffering from ill-health and unable to obtain suitable work. Granted £12 in 12 instalments.—Widow, aged 65, of L.F.P.S. Glasg., who practised at Rothesay and other places. Has a small pension from the Elder Fund, and earns a few pounds annually by letting rooms. Suffering recently from chronic rheumatism and sciatica and unable to attend to lodgers. Granted £12 in 12 instalments.—Widow, aged 58, of L.F.P.S. Glasg., who practised at Glasgow. Owing to ill-health and illness of daughter unable to work. Small allowance from brothers and sister and small pensions from the Elder Fund and the Skinners Company. Granted £10 in one instalment.—Daughter, aged 43, of M.R.C.S. Eng., who practised at Gillingham, Kent. Has recently been working as a general servant, but in consequence of ill-health and overwork requires a rest. A letter for a convalescent home procured for her, and a sum of £5 granted, to be given at the discretion of a local charity.—Widow, aged 57, of M.D. Durh., who practised at Peckham Rye. Only income the proceeds of the sale of late husband's practice, which is being carried over several years. Paralysed and nearly blind and quite unable to move without help. Granted £12 in 12 instalments.—M.D., of St. Andrews, aged 76. Practised at London, Norfolk, and abroad. Obtains very occasionally locum work. Lost small capital in struggle to obtain work and ill health. Granted £18 in 12 instalments.—Widow, aged 62, of M.R.C.S. Eng., who practised at Streatham Hill. Since husband's death income only £24 per annum, and owing to husband's long illness practice entirely lost and of no financial value. Granted £12 in 12 instalments.—Widow, aged 75, of L.R.C.P. Edin., who practised in Ireland. Has with the assistance of daughters tried to run a nursing home in South-West London, but owing to lack of patients has got behind with rent. Income £30 per annum from Epsom College. Relieved once, £10. Granted £10, to be paid through the Guild visitor.—Daughter, aged 52, of M.R.C.S. Eng., who practised at Newport, Mon. Receives occasional help from friends. Is almost blind and health very bad. Relieved three times, £35. Granted £12 in 12 instalments.—Daughter, aged 70, of M.R.C.S. Eng., who practised at Limehouse. Earns a little by keeping poultry and other general work, and receives a little help from nephew. Health very uncertain. Relieved once, £10. Granted £12 in 12 instalments, and recommended to apply for the old age pension.—Widow, aged 73, of M.D. Glasg., who practised in Ireland and other places. Lives in own house, and lets off two flats which when occupied enables her to manage. In consequence of one flat having been empty become short of money to pay taxes and rates. The case referred to the Guild. Relieved seven times, £41. Granted £5.—Widow, aged 57, of M.R.C.S. Eng., who practised at Maida Vale. No income, and suffers from chronic rheumatism and weak heart. Relieved 10 times, £104. Granted £12 in 12 instalments.—Daughter, aged 60, of M.R.C.S. Eng., who practised at Nevin. Earns a little by letting rooms, and has to keep her sister, who is in very delicate health. Relieved eight times, £86. Granted £12 in 12 instalments.—Widow, aged 50, of M.B. Aberd., who practised in Warwickshire and New South Wales. Receives a little help from her sister and son, but is suffering from general illness and quite unable to work. Relieved six times, £56. Granted £12 in 12 instalments.—Daughter, aged 67, of M.R.C.S. Eng., who practised at Cranbrook, Kent. Health bad and quite unable to look after herself. Has an annuity of £16 9s. 8d. and a little help from the Kent Benevolent Society. Relieved seven times, £84. Granted £12 in 12 instalments.—Daughter, aged 63, of L.S.A. Lond., who practised at Kilburn and Regent's Park. Health very bad and has to keep a sister. Recently lost a friend who paid the rent and assisted otherwise. Relieved five times, £60. Granted £12 in 12 instalments.—Widow, aged 44, of M.B., C.M. Edin., who practised at Ballindalloch. At husband's death was left with four young children, the eldest of whom is now 15 years old. Has tried to earn a living by taking in boarders, but owing to the recent illness of self and children has been unable to properly attend to this. Receives £15 per year from the Flemming Fund. Relieved three times, £30. Granted £10 in two instalments.—Widow, aged 44, of L.S.A. Lond., who practised in London. Has been trying to make a living by letting rooms, but has not been successful, and owes rent. Three children, the youngest of whom is six years old. Relieved twice, £12. Voted £3 as a special grant.—M.D., of Aberdeen, aged 61, practised at Walsall and other places. Suffering from lateral sclerosis and paralysis since 1831. Income from various sources £70 per annum. Three children, the youngest 3 years and the oldest 15 years. Relieved six times, £53. Granted £12 in 12 instalments.—Orphan, aged 63, of M.R.C.S. Eng., who practised in Harley-street, W. Too old to obtain employment. Receives pension from another society of £25 and some help from the Guild. Relieved twice, £24. Granted £12 in 12 instalments.—Widow, aged 69, of M.R.C.S. Eng., who practised in Stratford, E. Has pension of £30 from Epsom College, but health very bad. Relieved four times, £39. Granted £10 in two instalments.—Widow, aged 71, of L.R.C.P. Edin., who practised at Sparkbrook, Birmingham. Only income £16 per annum and a little help from children. Has tried to augment this by taking in boarders, but owing to age and bad health unable to make this pay, and the rent and taxes are in arrears. Relieved twice, £20. Granted £10.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Asylum Officers (Superannuation) Bill.

Lord **WOLMER** has introduced in the House of Commons a Bill "to limit the hours of employment of officers and servants in asylums and to amend the Asylum Officers Superannuation Act, 1909." It was read a first time.

Naval Medical Compassionate Fund Bill.

Mr. G. **LAMBERT**, the Civil Lord of the Admiralty, on Tuesday, May 12th, introduced a Bill "to make further and better provision with regard to the Naval Medical Compassionate Fund." It was read a first time.

HOUSE OF LORDS.

THURSDAY, MAY 7TH.

Midwives (Scotland) Bill.

THE House went into Committee (for the second time) on the Midwives (Scotland) Bill.

Lord **BALFOUR** of **BURLEIGH**, in moving the adoption of a series of amendments *en bloc*, explained that with one exception they were of a drafting character. As the Bill stood there was a provision that on the formation of a Central Midwives Board in Scotland three members were to be appointed by the President of the Council, and two of these when available should be certified midwives practising in Scotland under the terms of the Bill. Of course, these midwives were not available now, and it was uncertain when they would be. Therefore, after conference with the Scottish Office and the Privy Council, it had been suggested that he should make the Privy Council responsible for the formation of the Board for a period of years. That would get over the difficulty. He also proposed to insert specific provisions that the new Board should elect a chairman from among its own members and that the sittings should take place in Edinburgh.

All the amendments were agreed to and the Bill was reported to the House.

HOUSE OF COMMONS.

WEDNESDAY, MAY 6TH.

Infants Milk Bill.

Mr. **DOUGLAS HALL** moved for leave to bring in a Bill "to ensure the supply of milk to certain persons." He said that the aim of the Bill was to ensure the sale of pure milk to certain mothers of infant children at a price which they could afford to pay. The measure would increase the supply of pure milk from dairy farmers, and it would cost the community but a trifling sum, if anything. It was proposed to make use of the local authorities and the medical officers of health as agents for groups of mothers in districts to enable them to obtain milk at a price which they could afford to pay. In the event of any jobbery or corruption it was proposed that the Local Government Board should fix the price of the milk to be thus sold. It was stipulated that it was to be pure. The best definition was that contained in the Sale of Milk Regulations Act, 1901, and it was proposed that this definition should be altered in future if there was a statutory definition better defining what pure milk was. Having referred to the insufficiency, or even the entire lack, of nourishing milk in the budget of the very poor, the honourable Member proceeded to say that his Bill laid down that the local authority, through their officer of health, should provide milk to certain mothers in their district belonging to the poorer classes. The Bill defined these mothers as mothers who came under the maternity benefit of the National Insurance Act. The time during which they could obtain the milk was to be limited, say, to three months after the birth of the child. Even in the country districts it was difficult for mothers to obtain milk. In many districts farmers sent the whole to the large towns for sale, and it was almost impossible to get milk in those districts. If the Bill passed, the local medical officer could make arrangements with some dairy farmer and make it worth his while to keep back sufficient to be sold to these mothers. If there was a slight loss on the purchase—he did not believe that there would be—it would be borne by the local authority. He recommended the Bill to the House as a short, simple, practical, and inexpensive contribution to the great question of public health and the physical fitness of the nation.

Leave having been granted, the honourable Member brought in the Bill. He has the support of Lord **HENRY CAVENDISH-BENTINCK**, Mr. **CHARLES BATHURST**, Mr. **ASTOR**, Mr. **GRANT**, and Mr. **JOYNSON-HICKS**.

THURSDAY, MAY 7TH.

Domiciliary Treatment in Middlesex.

Mr. **WORTHINGTON EVANS** asked the honourable Member for St. George's-in-the-East as representing the Insurance Commissioners whether he was aware that the Middlesex Insurance Committee was refusing to carry out its tuberculosis officer's recommendation that no insured person should receive domiciliary treatment with extras unless the insured person had chosen a panel doctor; and whether, in a case where an insured person had provided and paid for his own medical man, who was willing to act in consultation with the tuberculosis officer, it was the intention of the Government that the insured person was to forfeit the extras under the sanatorium benefit which the tuberculosis officer recommended.—Mr. **WEDGWOOD BENN** said in reply: The recommendation of an Insurance Committee for sanatorium benefit and the nature of the treatment provided thereunder is, as the honourable Member is aware, a matter for the discretion of the committee. My right honourable friend is informed, however, that no such advice as the honourable Member suggests has been given by the tuberculosis officer referred to.

MONDAY, MAY 11TH.

Payment of Panel Practitioners.

Mr. **FELL** asked the honourable Member for St. George's-in-the-East why some better arrangement was not made for the payment of the panel doctors under the National Insurance Act; and would he say why money due was paid by driblets and was nearly always in arrear for periods of weeks, which treatment of the doctors did not conduce to efficient and satisfactory work by them.—Mr. **WEDGWOOD BENN** replied: As payments to doctors during the year are advances on account of remuneration which could not be determined till the end of the year, a margin must necessarily be reserved for the final settlement. It will, however, be possible for Insurance Committees in many cases to reduce the margin reserved when the accounts for last year are completed and more precise information is accordingly forthcoming as to the actual sums available.

TUESDAY, MAY 12TH.

The Largest Panel List.

Replying to Sir J. D. **REES** and Mr. F. **WHYTE**, Mr. **WEDGWOOD BENN** said: The maximum number of insured persons on the list of any single medical man on the panel in Great Britain is 5455.

Mr. F. **WHYTE**: Does the honourable gentleman mean a single medical man or one having an assistant?—Mr. **WEDGWOOD BENN**: He is the only medical man on the panel in respect of those persons, but as a matter of fact he has two assistants.

Treatment by Herbalist Practitioners.

Mr. **BRASSEY** asked the honourable Member for St. George's-in-the-East whether his attention had been called to the action of the Southport and other Local Insurance Committees in refusing to allow insured persons to make arrangements for medical treatment by herbalist practitioners notwithstanding that the Approved Societies to which the insured persons belonged were paying sickness benefit on the certificates of such practitioners; and what action he proposed to take in the matter.—Mr. WEDGWOOD BENN said in reply: As I have previously stated, the question of granting or refusing permission to insured persons to make their own arrangements under Section 15 (3) of the National Insurance Act, 1911, is a matter for the discretion of Insurance Committees, and my right honourable friend cannot interfere in the exercise of that discretion.

Milk and Dairies Bill.

Mr. H. SAMUEL, in moving for leave to present a Bill "to make better provision with respect to the sale of milk and the regulation of dairies," said that the general law in this country in relation to milk had regard chiefly to the prevention of fraud and to the checking of deliberate adulteration. It had so far had very little regard to the more important matter of the health of the people. Experts and authorities had reported that tuberculosis was undoubtedly spread, particularly amongst children, by the consumption of tuberculous milk. The Royal Commission on Tuberculosis and the Departmental Committee known as the Astor Committee reported in this sense. There were in England and Wales about 53,000 cases of tuberculosis every year, and no fewer than a fourth of them were non-pulmonary tuberculosis amongst children, and a not inconsiderable proportion of these was due to milk. Although infinite care was taken in this country as to the water-supply, yet the safeguarding of the milk-supply, which was of equal importance, was little regarded by the law. About a hundred local authorities had now secured powers to protect their population from contaminated milk, but the result was a multiplication of inspection in rural districts, much to the disgust of the farmers. It had been recognised in all quarters of the House that this was a matter which demanded legislation. The subject of milk, however, which ought to be a peaceful topic—the very name of it summoned up ideas of what was meek and mild—had been a matter of hot and almost burning controversy. There were great interests concerned. The public health authorities, especially of the towns, were eager to safeguard the health of the population under their care, and they were unwilling to surrender the powers which had been conferred upon them by local Acts, unless they could be sure that a really efficient system of protection and control would be established in the rural districts. The milk-selling industry was a numerous and highly organised body which was conducting a trade of inestimable value to the community. They were anxious to see that the purity of the milk-supply was secured, but at the same time they were, not unnaturally, anxious to secure that they should not in the conduct of their business be unnecessarily harassed by regulations and especially they were anxious to secure that the members of the milk-selling trade should not be punished for faults which they had not themselves committed because they were the parties most easy to reach. Thirdly, there was the great agricultural industry which was equally eager to observe any practical measures for safeguarding the health of the population and to maintain the reputation of the milk industry, but the members of that industry did very strongly object to the present system of multiple inspection, and they were timid lest they should be exposed to harassing and impracticable regulations. They were especially timid lest their industry should be put to great expense by the adoption of measures pressed forward by idealists. He had been in communication with the representatives of all those interested. He found that each of them was anxious to see legislation, and to have the whole matter put upon a more satisfactory footing. He had endeavoured to frame a Bill which would meet with the general assent of the various authorities concerned. The Bill was of a detailed character, and it was not possible for him within the short time at his disposal to describe the somewhat numerous and certainly very detailed clauses. It would be enough to say now that it proposed to make Regulations in order to prevent the supply of contaminated and dirty milk, and these Regulations should be made by the Local Government Board with the concurrence of the Board of Agriculture, who would be asked in this matter to act in coöperation with the Local Government Board. These Regulations would be laid before Parliament and they would not become operative if either House passed an address against them. He was thus taking every step to prevent unreasonable Regulations. The Bill proposed to provide means for tracing diseased milk back to its source and for stopping the source of such milk. Where there was adulteration the Bill enabled improved procedure to be adopted to bring the offence home to the guilty persons. It proposed also to get rid of multiple inspection and to apply similar regulations to foreign milk imported into our towns. He should make it clear that the Board of Agriculture proposed to compensate farmers for the cows that had to be slaughtered for tuberculosis on a somewhat more generous scale than hitherto. The Public Health grants which were proposed this year would provide for paying not only half the salaries of medical officers, but those of veterinary surgeons and milk inspectors. Therefore half of these expenses would be paid out of national funds. He should most carefully consider any amendments or suggestions which might be made by persons interested in the measure with a view to meeting all the interests concerned. For five years Bills on this subject had been before Parliament. He hoped that this session Parliament would be ready to deal with a subject which it was admitted on all hands demanded the attention of Parliament.

Leave having been granted, Mr. SAMUEL brought in the Bill, which was read a first time.

SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per annum, with apartments, board, lodging, and washing.

SHEFFIELD, JESSOP HOSPITAL FOR WOMEN.—Assistant House Surgeon, unmarried. Salary £80 per annum, with board, residence, and laundry.

SHEFFIELD ROYAL INFIRMARY.—Ophthalmic House Surgeon for six months. Salary £80 per annum, with board and residence.

SHEFFIELD UNION HOSPITAL, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, rations, &c.

SHREWSBURY, SALOP INFIRMARY.—House Physician. Salary at rate of £90 per annum, with board and apartments.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon. Salary at rate of £120 per annum, with rooms, board, and washing.

SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Second Assistant Medical Officer and Third Assistant Medical Officer. Salary at rate of £170 and £160 per annum respectively, with board, lodging, and washing.

STROUD GENERAL HOSPITAL.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

SWANSEA EDUCATION COMMITTEE.—Dental Surgeon. Salary £220 per annum.

SWANSEA GENERAL AND EYE HOSPITAL.—Two House Surgeons. Salary £125 per annum, with board, washing, and attendance.

WALSALL AND DISTRICT HOSPITAL.—Senior House Surgeon and Assistant House Surgeon. Salary £150 and £110 per annum respectively, with board, residence, and laundry.

WEST HAM AND EASTERN GENERAL HOSPITAL.—Junior House Physician and Junior House Surgeon. Salary at rate of £75 per annum, with board, residence, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Second Resident Casualty Officer. Board, lodging, and laundry provided. Also Two Assistant Anæsthetists.

WESTMINSTER HOSPITAL.—Honorary Administrator of Anæsthetics.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Senior House Surgeon. Salary £170 per annum, with board, apartments, and washing. Also Junior House Surgeon. Salary £150 per annum, with board, apartments, and washing.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

YORK, NORTH RIDING ASYLUM, Clifton.—Assistant Medical Officer. Salary £200 per annum, with board, apartments, washing, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

BENTLEY.—On April 28th, at "Haworth," Mitcham, the wife of Harold Bentley, M.R.C.S., L.R.C.P., of a son.

BLAKEWAY.—On May 4th, at Weymouth-street, W., the wife of Harry Blakeway, M.S., F.R.C.S., of a daughter.

MARRIAGES.

SPAIN—YATES.—On May 7th, at St. Andrew's Church, Stamford Hill, N., *Harold Gordon* Spain, L.D.S. R.C.S. Eng., to Cecile Belle Gladys Yates, youngest daughter of Mrs. J. C. Yates, of Stamford Hill, N.

DEATHS.

AMBROSE.—On May 7th, George Patrick Ambrose, M.D., M.R.C.S., L.R.C.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE BOY SCOUT MOVEMENT.

SIR Robert Baden-Powell addresses to us an appeal in which he points out that we as a nation spend annually 30 millions in training youths up to the age of 14 in reading, writing, and arithmetic (plus a modicum of physical drill) so that they may make good citizens, and then abandon them at the cross-roads of life to drift. Then we spend 38 millions more to correct the results of their drifting into crime and imprisonment, vice and sickness, poverty and unemployableness. This waste the Scout movement aims to counteract by supplying outside the school walls character training, health development, handicrafts and service for others, and by retaining a hold over the boy after he leaves school during the critical years of life. An endowment of £10,000 a year—say a capital fund of a quarter of a million—would render it possible greatly to extend this work so as to include in its training the mass of boys, even the waste material of the slums. Of this sum £65,000 have already been subscribed, and if there is a reasonable prospect of obtaining the balance by Whitsuntide the further development of the movement can be proceeded with. This is not sought as a charity, but as an insurance by the nation against its present waste of men and money by providing the country in the coming generation with a manly and characterful race. We publish in our correspondence columns this week an eloquent letter upon the same subject from Sir Lauder Brunton, whose advocacy we are sure will meet with a ready response from members of the medical profession.

"MARRIAGES" BETWEEN THE SAME SEX.

A CASE was reported last week of a girl who has been posing as a man for the past ten years in Milwaukee and "marrying" two girl friends. It was the second "marriage," apparently, which caused the secret to be divulged. In THE LANCET of June 23rd, 1900, p. 1814, we published an annotation with the title which stands at the head of this paragraph. Many such remarkable "marriages" have occurred, and not all by any means have been discovered. A few years ago there died a woman who had lived as a married man for 40 years. One interpretation of these episodes leaps to the medical eye, but a more commonsense and probable explanation of them is that the assumption of the male sex means higher wages for one member of a partnership.

"MILLIBARS."

To the Editor of THE LANCET.

SIR,—In answer to your correspondent "Beta," whose letter under the above heading appears in THE LANCET of May 9th (p. 1369), I will endeavour to explain how the "unit" on the new scale for measuring atmospheric pressure has been arrived at.

The centimetre-gramme-second (C.G.S.) system of units is based on the metric system, and gets its name from the primary units of length, mass, and time. This C.G.S. system has long been used universally for electrical and magnetic measurements. It is now being extended to meteorological measurements.

The unit of *pressure* in the C.G.S. system is a dyne per square centimetre. A dyne, or the unit of force, is the force which produces an acceleration of 1 centimetre per second (the unit of acceleration) in a mass of 1 gramme. A megadyne—that is, 1,000,000 dynes—per square centimetre is called a "bar" or "barye," a name which was agreed upon for this unit at the Conference of Physicists in Paris in the year 1900. A "millibar," similarly, is the 1000th part of a "bar," or 0·001 of the C.G.S. unit of pressure.

The accepted normal pressure of the atmosphere, or "standard atmosphere," is that of a column of mercury 76 centimetres (or, as "Beta" writes it, 760 millimetres) high at the freezing point of water, under the conditions as to gravitation which are to be found in latitude 45° N. or S. For other latitudes a small correction is necessary to allow for the difference of gravity. This pressure of a "standard atmosphere" is 1,013,193 dynes per square centimetre, or approximately 1·013 megadynes per square centimetre.

The *practical unit* of atmospheric pressure in the C.G.S. system is the megadyne per square centimetre, which may be called the "C.G.S. atmosphere." It is equivalent to a pressure of 750·1 millimetres of mercury (29·53 inches) at the freezing point of water in latitude 45°, and is the normal air pressure at 106 metres (348 feet) above sea level.

We have now seen that the *absolute unit* of pressure on the C.G.S. system is the dyne per square centimetre. As this unit is exceedingly small a *practical unit* 1,000,000 times as reat has been suggested. This unit, the megadyne per quare centimetre, is called a "bar." In the Daily Weather ,eport issued by the Meteorological Office, South Kensing-on, the centibar and the millibar respectively—that is, the ıundredth and the thousandth part of the bar—have been .dopted as working units of atmospheric pressure since ·Iay 1st, 1914. A barometric reading of 100 centibars, or 000 millibars, is equivalent to 29·53 mercury inches; one of 05 centibars, or 1050 millibars, equals 31 inches, and—in the ıpposite or downward direction—one of 97 centibars, or 70 millibars, would represent 28·65 inches.

Observers for the Meteorological Office have been furnished ·ith tables for converting from British to metric units and ·ice versâ, and the conversion is thereby rendered quite an ·asy matter.

I am, Sir, yours faithfully,

JOHN W. MOORE, M.D. Dub., F.R.Met.Soc.

Dublin, May 9th, 1914.

THE HEALTH OF THE PHILIPPINES.

IN the report of the Bureau of Health of the Philippine Islands for the last quarter of 1913 Dr. Heiser relates that there are now more than 60,000 fewer deaths per annum in the Philippines than in 1905, the reduction being mainly in preventable diseases. A 60 bed general hospital has been opened in Cebu. Four persons were discharged from the San Lazaro Hospital after having been apparently cured of leprosy for over two years. Cholera has been under better control than at any previous time. Cholera vibrio carriers were found in every district where the disease occurred. Measures against plague have been successful, for only one case of human plague occurred and no plague-infected rats were found. Rabies is present among dogs, but a soldier and a child bitten by a rabid dog received the Pasteur treatment and no ill-effects have yet appeared.

A DISCLAIMER.

Dr. Edwin L. Ash writes to say that the reference to the London Nerve Clinic contained in a letter in the early editions of the *Pall Mall Gazette* of May 5th was published without his knowledge or consent. On its being brought to his notice he immediately protested to the writer of the letter and endeavoured to prevent its further publication. The offending notice did not appear in the evening editions of the journal mentioned.

IS SILICOSIS AN ACCIDENT?

A. G. W.—Our correspondent asks whether silicosis in a metalliferous miner would be considered an accident under the Workmen's Compensation Act. The reply is that no form of fibrosis is included in the list of scheduled diseases to which this Act applies; therefore no successful claims for compensation under the Act can be made in respect of silicosis. Further, silicosis from its nature could not reasonably be looked upon as an accident in any ordinary sense of that word.

MEDICINE AND MUSIC.

A CORRESPONDENT writes: "On Saturday last, at the Royal Academy of Music, where Dr. and Mrs. Dundas Grant now continue their friendly orchestral meetings held for many years at Cavendish-square, their amateur orchestra, which numbers upwards of 90 members, 20 of them belonging to the medical profession, conveyed their thanks to their hostess and their congratulations to their conductor upon his recent recovery from illness, by the presentation of a floral tribute and of a Japanese dwarf tree as a lasting symbol of their appreciation."

ANTITYPHOID INOCULATION IN BRITISH COLUMBIA.

Dr. Bapty, acting provincial health officer of British Columbia, has published a letter on typhoid prevention in which he quotes the results obtained by Dr. H. G. MacKid, surgeon-general of the Alberta division of the Canadian Pacific Railway. In 1912-13 amongst 13,900 men inoculated only 3 cases occurred, while 6500 men not inoculated showed 236 cases. Vaccine is being distributed free of charge by the Government of British Columbia, which hopes thus to reduce the heavy toll of life and money taken annually by this disease. 700 cases occur annually, costing some £16,000 in hospital charges and losing the patients some £50,000 of wages in the year. Moreover, amongst these 700 cases there were 85 deaths.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Prof. W. M. Hicks: On the Effect of the Magneton in the Scattering of α Rays.—Hon. R. J. Strutt: Luminous Vapours Distilled from the Arc, with Applications to the Study of Spectrum Series and their Origin. I.—Mr. W. T. Pawlow: On the Ionisation of Gases by Collision and the Ionising Potential for Positive Ions and Negative Corpuscles (communicated by Sir J. J. Thomson).—Mr. C. E. Stromeyer: The Determination of Elastic Limits under Alternating Stress Conditions (communicated by Prof. W. E. Dalby).—Mr. G. W. C. Kaye and Mr. W. F. Higgins: The Emission of Electricity from Various Substances at High Temperatures (communicated by Dr. R. T. Glazebrook).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF THERAPEUTICS AND PHARMACOLOGY (Hon. Secretaries: W. Langdon Brown, Philip Hamill): at 4.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1914–1915.

Paper:

Dr. E. W. Ainley Walker and Prof. Georges Dreyer: The Dosage of Drugs, Toxins, and Antitoxins.

GENERAL MEETING OF FELLOWS at 5 P.M.

Ballot for Candidates for Fellowship.

SECTION OF PSYCHIATRY (Hon. Secretaries—R. H. Cole, Bernard Hart): at 5.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1914–1915.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—J. M. H. MacLeod, S. E. Dore): at 4 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1914–1915.

Demonstration (at 4.15 P.M.):

Cases of Mycosis Fungoides.

Debate (at 5 P.M.):

On Mycosis Fungoides (to be opened by Dr. J. H. Sequeira).

Members intending to take part in the debate are requested to communicate with the Hon. Secretaries.

7.30 P.M., Annual Dinner at the Imperial Restaurant, Regent-street, W.

Members are specially requested to notify the Senior Hon. Secretary if they intend to be present, and to give the names of their guests.

SECTION OF NEUROLOGY (Hon. Secretaries—T. Grainger Stewart, H. Campbell Thomson): at 8.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1914–1915.

Paper:

Dr. Ivor J. Davies: The Senghenydd Explosion from a Medical Standpoint.

CLINICAL SECTION.—The Members are specially invited to attend the Meeting of the Section of Neurology.

SECTION OF DERMATOLOGY.—The Members are specially invited to attend the Meeting of the Section of Neurology.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—F. Langmead, Philip Turner, William J. Midelton): at 4.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1914–1915.

Short Papers:

Dr. F. Parkes Weber: A Familial Case of Splenomegalic Anæmia with Infantilism.

Major R. McCarrison, I.M.S.: Nervous Cretinism.

SECTION OF ANÆSTHETICS (Hon. Secretaries—H. E. G. Boyle, Cecil Hughes): at 5.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1914–1915.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1914–1915.

Paper:

Lieut.-Colonel Wilkinson, I.M.S.: Tuberculosis in India.

SATURDAY.

SECTION OF BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—Chas. W. Buckley, J. Campbell McClure).

Provincial Meeting at Leamington.

(Full particulars have already been issued to Members of the Section.)

Annual General Meeting.—Election of Officers and Council for Session 1914–1915.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—Annual Oration:—Mr. R. Jones. Conversazione.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Paper:—Dr. W. A. Brend: A supposed Death from Tight-lacing in a Male.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Cases will be shown. 5.15 P.M., Laboratory Demonstration and Exhibit:—Mr. F. Curry: *Tuberculins, their Preparation and Standardisation.*

ROYAL SOCIETY OF ARTS, *John-street, Adelphi, W.C.*

THURSDAY.—4.30 P.M., Mr. E. A. Gait: The Indian Census of 1911: *Ethnography and Occupations.*

WIMBLEDON AND DISTRICT MEDICAL SOCIETY, Johnston's Rooms, 6, Broadway, Wimbledon, S.W.

FRIDAY.—9 P.M., Annual General Meeting. Election of President, Officers, and Committee. Address:—Mr. J. F. Colyer: Pyorrhœa Alveolaris, its Local and General Effects.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. M. H. MacLeod: Clinique (Skin). 5.15 P.M., Lecture:—Mr. H. J. Paterson: The Modern Treatment of Gastric Disease (lantern demonstration).

TUESDAY.—4 P.M., Dr. J. Galloway: Clinique (Medical). 5.15 P.M., Lecture:—Mr. L. Norbury: Pruritus Ani.

WEDNESDAY.—4 P.M., Mr. H. Lett: Clinique (Surgical). 5.15 P.M., Lecture:—*Dr. A. E. Giles: Diagnostic Aphorisms in Gynæcology.*

THURSDAY.—4 P.M., Mr. R. Davies-Colley: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. Sommerville: *Bio-chemistry and Medicine.*

FRIDAY.—4 P.M., Mr. T. B. Layton: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, *West London Hospital, Hammersmith-road, W.*

MONDAY.—10 A.M., Dr. Simson: *Diseases of Women.* 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman: Diseases of the Eye. 5 P.M., Lecture:—Dr. Beddard: Gastro-intestinal Ulceration.

TUESDAY.—10 A.M., *Dr. Robinson: Gynæcological Operations.* Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., *Medical and Surgical Clinics.* X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Beddard: Gastro-intestinal Ulceration.

WEDNESDAY.—10 A.M., *Dr. Saunders: Diseases of Children.* Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., *Mr. Souttar: Demonstration of Minor Operations.* 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women and Diseases of the Eye. 8 P.M., Conversazione.

THURSDAY.—9 A.M., Dr Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, *Lecture:—Dr. G. Stewart: Neurological Cases.* 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Mr. B. Harman: Diseases of the Eye. 5 P.M., Lecture:—Dr. Beddard: Gastro-intestinal Ulceration.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: *Diseases of the Skin.* 5 P.M., Lecture:—Dr. Beddard: Gastro-intestinal Ulceration.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. H. B. Carlill: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Throat, Nose, and Ear.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Dr. C. E. Zundel: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.15 P.M., Sir Malcolm Morris: Skin. 2.15 P.M., Special Lecture:—Mr. R. Carling: Gastro-enterostomy for Ulcer.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. H. B. Carlill: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. B. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. H. R. Prentice: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Sir James M. Davidson: Notes on Various Cases in which X Rays have been of Value in Diagnosis (illustrated).

FRIDAY.—Out-patient Demonstrations:—10 A.M., Dr. C. E. Zundel: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford: Medicine. 3.15 P.M., Mr. L. McGavin: Surgery. 2.15 P.M., Special Lecture:—Sir J. Rose Bradford: Angina.

SATURDAY.—Out-patient *Demonstrations:* 10 A.M., Dr. H. R. Prentice: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. B. Bickerton: Eye.——10 A.M., Col. Barry: Radiography.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham): Gynæcological (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Nose, Throat, and Ear (Mr. H. D. Gillies). X Ray and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. Dorell). 3 P.M., Clinical Pathology and Pathological *Demonstration (Dr. W. H. Duncan).* 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. Dorell). 3 P.M., Medical In-patient *(Dr. G. P. Chappel).* Clinical Pathology and Pathological Demonstration.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON), Albert Embankment, S.E.

Lectures in Advanced Medical Subjects:—

TUESDAY.—5 P.M., Dr. H. Maclean: Carbohydrate Metabolism in Health and in Diabetes.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON), *University-street, Gower-street, W.C.*

Lectures in Advanced Medical Subjects:—

FRIDAY.—5 P.M., *Dr. C. Bolton: Recent Observations upon Ulcer of the Stomach.*

GUY'S HOSPITAL MEDICAL SCHOOL, London Bridge, S.E.

Course of Lectures on Industrial Medicine:—

FRIDAY.—Lecture III.:—Dr. F. Shufflebotham: Miners' *Nystagmus,* with a Demonstration in Living Cases.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, Medical School, City-road, E.C.

MONDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Cardiac Department, Dr. Stott; Out-patient *Department, Dr. Phear, Dr. S. Thompson.* 3 P.M., Wards, Dr. Phear.

TUESDAY.—9 A.M., Laryngological Department, Mr. Mant. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. M. Leslie, Dr. B. King; Operations, Mr. A. Evans. 3 P.M., Wards, Dr. White. 4 P.M., Wards, Dr. M. Leslie

WEDNESDAY.—2 P.M., Wards, Dr. A. Davies; Out-patient Department, Dr. Drysdale, Dr. Kellie. 4 P.M., Wards, Dr. Drysdale. 4.30 P.M., *Roentgen Ray Department,* Dr. Jordan.

THURSDAY.—9.30 A.M., Dental Department, Mr. G. Thomson. 10 A.M., Cardiac Department, Dr. Stott. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. Phear, Dr. S. Thompson. 4.30 P.M. Laryngological Department, Mr. Mant.

FRIDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Wards, *Dr. Calvert;* Out-patient Department, Dr. M. Leslie, Dr. B. King. 5 P.M., Lecture-Demonstration:—Dr. Phear: Tumours of the Mediastinum.

SATURDAY.—10 A.M., Out-patient Department, Dr. Drysdale, Dr. Kellie. 11.30 A.M., Roentgen Ray Department, Dr. Jordan.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

Course of Lectures on Tuberculosis for Post-Graduates and Senior Students:—

MONDAY.—11 A.M., Prof. W. Bulloch: Bacteriology. 4 P.M., Mr. T. H. Openshaw: Caries of the Spine.

TUESDAY.—11 A.M., Dr. H. M. Turnbull: *Anatomy and Histology* (III.). 2 P.M., Mr. H. Lett: Tuberculosis of Bones. 4 P.M., Dr. S. G. Scott: *Radiography.*

WEDNESDAY.—11 A.M., Prof. W. Bulloch: *Heredity.* 2 P.M., Mr. H. M. Rigby: *Surgery of Tuberculosis of Lymphatic Glands.* 4 P.M., Mr. P. Furnivall: Surgery of *Tuberculosis of Alimentary* Tract.

THURSDAY.—11 A.M., Mr. R. Howard: Surgical Morbid Anatomy. 4 P.M., Sir Frederic Eve: Tuberculosis of Joints.

FRIDAY.—11 A.M., *Dr. P. N. Panton:* Examination of Excretions, Discharges, Effusions, &c. 2 P.M., Mr. F. S. Kidd: Genito-urinary Tuberculosis.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, *Brompton, S.W.*

WEDNESDAY.—4 P.M., Dr. Wall: Demonstration of Cases.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Taylor: Cases in the Ward.

FRIDAY.—3.30 P.M., Clinical Lecture:—*Dr. G. Stewart:* Compression Paraplegia.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY.—3 P.M., Lecture:—Dr. D. McKenzie: Some Adventures in the Mouth.

LONDON LOCK HOSPITAL, 91, Dean-street, Soho, W.

Special Course of Instruction in Venereal Diseases, *for Post-Graduates and Students, with* Practical Demonstrations of the Various Methods of Treatment:—

MONDAY.—Clinics:—1 P.M., Mr. Ryall; 6 P.M., Mr. Gibbs. 5 P.M., Lecture:—Mr. Gibbs: The Diagnosis of Gleet.

TUESDAY.—Clinics:—2 P.M., Mr. Lane; 6 P.M., Mr. Paterson.

WEDNESDAY.—Clinic:—6 P.M., Mr. Shillitoe.

SATURDAY.—Clinic:—2 P.M., Mr. McDonagh.

THE THROAT HOSPITAL, Golden-square, W.
MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.
TUESDAY.—MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES, Quay-street.—4.30 P.M., Dr. G. H. Lancashire: Pyogenic Skin Affections.
WEDNESDAY.—ROYAL INFIRMARY—4.30 P.M., Demonstration of Cases.
THURSDAY.—ANCOATS HOSPITAL—4.30 P.M., Dr. A. Renshaw: Intrathecal Injections of Neosalvarsan—The Luetin Reaction.

UNIVERSITY OF LEEDS, Great Hall of the University, College-road.
Special Lectures on Medical Subjects:—
WEDNESDAY.—4 P.M., Sir Thomas Oliver: Lead Poisoning from the Industrial and Medical Point of View.

For further particulars of the above Lectures, &c., see Advertisement Pages.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced. In 1914:—

May 1st–Nov. 1st (Lyons).—International Town Hygiene Exhibition.
" 15th–Oct. 15th (Berne).—Swiss National Exhibition.
" 18th–21st (London, Imperial Institute).—Victoria League Imperial Health Conference.
May–October (London, Shepherd's Bush).—Anglo-American Exposition.
June 8th–10th (Berne).—Seventh International Dairy Congress.
" 9th–12th (Birmingham).—National Council of Nurses' Annual Conference and Nursing Exhibition.
" 15th–18th (Portsmouth).—International Abolitionist Conference (Prostitution).

" 10th–12th (Fort William and Port Arthur, Ontario).—Fourth Annual Congress of the Canadian Public Health Association.
" 21st–26th (Victoria, B.C.).—Dominion Exhibition.
" 21st–26th (Vienna).—Third International Congress on Diseases of Occupation.
" 30th–Oct. 3rd (Brussels).—Fourteenth French Congress of Medicine.
Oct. 31st–Nov. 2nd (Berlin).—First Congress of the International Society for Sexual Research.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

A Report
OF
THE WORK AT THE RADIUM INSTITUTE FROM JAN. 1st TO DEC. 31st, 1913.

BY A. E. HAYWARD PINCH, F.R.C.S. ENG.,
MEDICAL SUPERINTENDENT AND GENERAL DIRECTOR OF THE RADIUM INSTITUTE.

With an Appendix on the Work of the Chemico-Physical Laboratory by W. L. S. ALTON, F.I.C.

(Published with the Authority of the Committee.)

THIS report deals with the cases which have presented themselves at the Radium Institute from Jan. 1st to Dec. 31st, 1913, inclusive. The experiences of the past year tend on the whole to confirm the conclusions set forth in the report of the first 17 months' work, but some few additional facts have been noticed, which serve to increase our knowledge in respect of the prognosis and treatment of various diseases.

TABLE I.—*Summary of Cases.*

Examined but not treated	112
Recently treated, and results not yet noted	176
Received prophylactic irradiation only	30
Apparently cured	56
Cured	18
Improved	341
Not improved	152
Abandoned treatment	50
Dead	37
Total	972

TABLE II.—*Classification of Cases.*

CARCINOMA.

Squamous-celled.

The results obtained in the treatment of epitheliomata affecting glabrous surfaces call for no fresh comment, and in suitable instances removal of the growth by radium may be confidently anticipated.

x

Epitheliomata of the buccal, lingual, and pharyngeal mucous membranes still prove both refractory and disappointing in their response to radium, but a new method of treatment has recently been devised which in instances of cancer of the tongue has given distinctly encouraging results; it consists in the burying within the carcinomatous nodule of a very small but intensely powerful radium emanation tube possessing an initial activity equivalent to that of 80 to 100 mgm. of radium bromide enveloped in a screen of 1 mm. of silver or 0·3 mm. of platinum, and giving an exposure of 24 hours' duration. A fairly severe reaction follows, and in some cases the nodule ceases to grow and becomes replaced by dense fibrous tissue.

Several cases of *epithelioma of the œsophagus* have been under treatment, but unfortunately the majority of these have been in so advanced a stage as to preclude all hope of success. In those instances, however, where complete occlusion had not occurred and it was possible to introduce radium actually into the lumen of the growth, distinct though temporary benefit has resulted, and that this effect is not merely a mechanical one due to the dilation of the stricture by the apparatus is evidenced by the fact that the improvement in the power of swallowing has persisted for six or even nine months after the termination of the treatment.

Carcinoma of the uterus still continues to yield most gratifying results, and the effects of radium treatment in inoperable cases are far in advance of those obtained by any other known medical or surgical methods. The local manifestations of the disease are benefited in the most striking fashion, and the complete disappearance of fungating growth, arrest of hæmorrhage and discharge, healing of ulceration and relief from pain, are phenomena of almost daily occurrence. In favourable cases, moreover, the treatment appears to exert a distinctly retarding influence on the dissemination of metastatic deposits and thus to arrest the progress of the disease. It is not possible, however, to speak of "cure" even in these latter instances.

Great care must be exercised in the treatment of recurrences which make their appearance within six months of the performance of a Wertheim's operation. The functions of the trophic nerves of the pelvis seem often to be seriously impaired by the extensive and elaborate dissection which is associated with this method of hysterectomy, and for this reason the amount of radium used should be small, not exceeding 50 mgm., the screening not less than 1·5 mm. of lead, and the total exposure not longer than 20 hours, spread over four or five days. Unless these precautions be observed a severe and extensive destructive reaction may follow the application of radium.

In all cases where radium is applied within the vagina the patient should be instructed to douche freely night and morning for at least six weeks after the termination of the treatment, as unless this be done an adhesive vaginitis not infrequently occurs. In some extremely susceptible subjects a transient proctitis has been noted to follow upon intravaginal treatment.

The screening employed in cases of carcinoma of the uterus is either 1 mm. of silver or 2 mm. of lead; but the thinner screening should only be adopted when the cervical canal is patulous and the tube can be introduced into its cavity.

Spheroidal-celled Carcinoma.

Carcinoma of the breast.—The number of patients with this disease applying for treatment far exceeds that of any other malignant condition.

The policy of declining to treat operable cases is still rigidly adhered to (unless the patients have absolutely refused to submit to operation), and radium is used as a last resource. Many patients exhibit a great susceptibility to radium, the primary growth becomes smaller, infected glands and subcutaneous nodules lessen or perhaps even disappear.

Little or no effect appears to be exerted in the prevention of metastatic deposits, though the treatment does not, at any rate, hasten their dissemination.

Some cases in which pleurisy, dependent upon carcinomatous invasion of the pleura, has been present have shown remarkable improvement; and the application of powerful apparatus screened with 2 mm. of lead over the affected pleura, after a preliminary paracentesis, has effectually prevented the further formation of pleuritic effusion.

A few patients have been under treatment at intervals of three or four months since the opening of the institute in September, 1911, and it has been noted that a stage in their treatment is reached sooner or later at which the response to radium fails and the benefit derived becomes negligible.

Small isolated recurrent nodules, inoperable by reason of their attachment to the sternum, clavicle, ribs, or rib cartilages, are best treated by burying a small powerful emanation tube screened with 1 mm. of silver in them for a period of 24 hours.

Carcinoma of thyroid.—Encouraging results have been obtained in the few instances that have come under notice; the progress of the disease has been arrested, and a decrease in the size of the existing growth has been obtained, the general discomfort and dysphagia when present being greatly relieved. The line of treatment employed has been the use of numerous powerful applicators screened with 2 mm. of lead, and so disposed over the surface of the growth as to obtain the maximal "cross-fire" irradiation. Burying of emanation tubes within the growth has not yet been adopted owing to the great tendency of these growths to fungate if any breach be made in the investing skin.

Paget's disease.—The superficial lesion in this condition is usually speedily cured by one hour's exposure to a half strength plate unscreened, but the underlying induration and affection of glands, if present, require prolonged treatment with heavily screened applicators if any real benefit is to be obtained. In cases where the patient is willing to submit to operation this procedure should always be adopted.

Columnar-celled Carcinoma.

Carcinoma of rectum.—This disease displays much variation in its response to radium therapy, and numerous factors have to be considered in prognosis. Speaking generally, the soft annular and vascular type of growth is much more favourably affected than the flat, hard, non-annular plaque with much subjacent induration. In the treatment of this latter class of growth the action of the gamma rays (which it is impossible to prevent) on the healthy rectal mucous membrane opposite the plaque produces a proctitis, which, though generally transient, sometimes proves both persistent and severe, and adds greatly to the patient's discomfort. In the treatment of the former type, if the radium tube be of proper dimensions and introduced accurately within the lumen of the growth, little or no healthy mucous membrane is affected by the gamma rays, and no proctitis occurs.

Growths situated in the upper half of the rectum appear to be more amenable to treatment than when in the lower, though this may be due to the fact that tenesmus is always more constant and severe when the growth is near the sphincters.

The performance of a colostomy before radium treatment is often advisable, as the constant passage of fæces over a surface that is reacting to radium frequently causes much pain.

Idiosyncrasy is sometimes responsible for curious results. Some patients are extremely susceptible to the action of radium, and proctitis appears quickly, is very severe, and persists for a long time. With others the reaction sometimes takes six or eight weeks to develop, proceeds exceedingly slowly, and does not disappear for two or three months.

The routine method of treatment consists of a 30-hour exposure—five days of six hours each—with a tube containing 100 mgm. of radium bromide, screened with 2 mm. of lead and 3 mm. of rubber, and applied in actual contact with the growth, the series of exposure being repeated at the end of six weeks. If the patient proves extremely susceptible smaller doses are given at shorter intervals. In the most favourable cases the carcinomatous material shrinks and becomes replaced by dense fibrous tissue. In instances where the original growth has been of the annular type a fibrous stricture will result, which will need frequent and regular dilatation.

Carcinoma of prostate.—The number of cases of this condition which have been treated up to the present is not very large, but benefit has been noted in all of them. Hæmaturia when existent has been either diminished or abolished, pain has been greatly lessened, and the size of the growth decreased. Various methods of treatment have had to be adopted according to the nature of the case. When catheterisation can be well tolerated a 50 mgm. tube of radium bromide in a "window" screen of 1 *mm.* of silver and 1 mm. of lead is introduced per urethram and maintained in actual contact with the growth for a period of two hours a day on five successive days, and its action is supplemented by another tube of 100 mgm. in a screen of 2 mm. of lead, introduced into the rectum for six hours a day on five successive days. When catheterisation is not practicable or advisable the action of the rectal tube is reinforced by a powerful flat applicator screened with 2 mm. of lead and placed either on the perineum or over the pubes.

Carcinoma of bladder.—Nine cases of this disease have been treated and in six instances the results have been most gratifying. The hæmaturia, cystitis, and all subjective symptoms have disappeared and cystoscopic examination has shown that the size of the growth has been greatly lessened and any ulcerated surface has become covered with healthy epithelium.

The treatment has consisted of the introduction of a 50 mgm. tube of radium bromide in a "window" screen of 1 mm. of silver and 1 mm. of lead inserted per urethram, and maintained by means of a pliable silver wire in such a position that the window-side of the apparatus is in actual contact with the growth. If the lesion be on the base of the bladder a second tube screened with 2 mm. of lead is placed in the vagina in female and in the rectum in male patients, but if on the anterior bladder wall a flat applicator similarly screened is fixed over the pubic region. The usual length of exposure is 10 hours intravesically in five days of two hours each, and 30 hours with the vaginal, rectal, or pubic applicators spaced over the same number of days.

Rodent ulcer.

Little has been added to our knowledge of the treatment of this condition, but when dealing with the question of prognosis it appears justifiable to divide rodent ulcers into two definite clinical types: (1) The hypertrophic nodular type, with slight superficial ulceration of a scaly character (this class responds extremely well to radium and yields most satisfactory results); and (2) the excavating type, with undermined and overhanging edges and a gelatinous base (this not infrequently proves very intractable and repair is most difficult to effect). Whenever the size and situation of the ulcer permit, it is best to give one powerful unscreened exposure, a full strength plate being applied in actual contact with the ulcer for one, two, or three hours, according to circumstances. One such treatment usually suffices to produce an apparent cure. Exposures of short duration repeated at frequent intervals are not nearly so effectual, and instances have been met with where the adoption of this procedure appears to have been responsible for the development of an epithelioma on the site of the original ulcer.

Rodent ulcers attacking cartilage, bone, or mucous membranes are very refractory; though an exception should be made with regard to the orbital mucosa, which is generally very amenable to the action of radium.

SARCOMATA AND OTHER CONDITIONS.

Speaking in general terms, *sarcomata*, if taken in their early stages and before dissemination has occurred, do very well under radium treatment. The burying within the growth of tubes of radium salts or radium emanation should be resorted to whenever practicable, and the action of these tubes may be much helped by the external application of radium plates heavily screened. It is important to use a large quantity of radium and to give a heavy dosage. Small doses should be avoided as they exert a distinctly irritating effect and stimulate the growth of the tumour. The best results are obtained in sarcomata of the tonsil and post-nasal space, and the results in many such cases are amazing, the growths completely disappearing within six weeks of the treatment. Lymphosarcomata also give excellent results. Melanotic sarcomata are not influenced by radium, and in the few cases that have been treated no benefit has been observed.

Lymphadenoma.—When the disease is localised and confined to one or more small superficial areas, the disappearance of the enlarged glands is frequently brought about by the use of radium, and the progress of the disease is thus arrested. When, however, the condition is generalised the employment of numerous large and powerful applicators becomes necessary, and this heavy dosage is almost always followed by severe systemic disturbance with high temperature and general malaise. After the reaction has subsided considerable improvement is often apparent, but this is only temporary in character, and the condition sooner or later returns with increased severity.

Mediastinal tumours.—In almost every instance that has come under observation the rate of growth has been very markedly checked by the use of radium, and in one or two cases a definite decrease in the size of the tumour—as seen by X ray screening—has undoubtedly occurred. If the condition be accompanied by an accumulation of fluid in the pleura, and paracentesis be performed, radium appears to exert a very remarkable action in lessening the tendency to the production of further effusion. In these cases the use of a very large quantity of radium (400–500 mgm.) is indicated; the applicators should be screened with 2 mm. of lead and disposed in such fashion over the chest wall as to procure the maximum "cross-fire" irradiation.

Treatment must be very persistent, a total exposure of not less than 30 hours should be given, and the series repeated at the end of four weeks. This heavy dosage is almost invariably followed in two or three days by a feeling of great fatigue and exhaustion, but this condition passes off completely in about a week's time.

Fibroid disease of the uterus.—Radium exerts a most beneficial action upon the distressing symptoms, menorrhagia and metrorrhagia, which are the almost invariable concomitants of this condition, though it seldom produces any very great diminution in the size of the uterus. As the cervical canal is rarely sufficiently patulous to admit a screened radium tube without previous dilatation, and patients are often averse from this, the treatment may be carried out by the introduction of a tube containing 100 mgm. of radium screened with 2 mm. of lead into the posterior fornix, and applying a plate of from 80 to 100 mgm. similarly screened over the fundus uteri. The total exposure should be between 30 and 60 hours, spread over from five to ten days, and the series should be repeated after six or eight weeks. The first effect noted is the checking of the metrorrhagia, and this is followed by a progressive decrease of the menorrhagia until the flow becomes normal or sometimes ceases altogether.

Leucoplakia.—Leucoplakic patches on the tongue, cheek, or vulva are speedily removed by radium, but they tend to recur sooner or later. Half-strength plates screened with 1/10 mm. of lead should be used, and exposures varying from one to three hours' duration, according to the thickness of the lesion, should be given. A slight superficial reaction takes place and the patches disappear.

Nævi and other Conditions.

Flat superficial nævi, capillary nævi, "port wine stains."—Before expressing an opinion as to the possibility of radium treatment effecting an improvement in any particular instance, it is advisable to subject the lesion to diascopy. If blanching be readily effected by gentle pressure the result of the treatment will probably be satisfactory; but if it be found impossible to produce blanching except by great pressure, it is unlikely that radium can do much for the condition. Infinite patience is necessary in the treatment of superficial nævi, and the utmost caution must be observed. The effect of each exposure should be most carefully studied, as too frequent treatments or excessive dosage may result in the production of troublesome telangiectases. It is better to use quarter or half strength applicators screened with 1/100 mm. of aluminium and to start with short exposures of from 15 to 20 minutes' duration, gradually increasing the length of the same until a satisfactory reaction has been obtained. So soon as the lesion has assumed a salmon-pink colour the screening should be altered to 1/10 or 2/10 mm. of lead, and the length of exposure increased to one, one and a half, or two hours.

Cavernous nævi.—These do excellently under radium, especially when of such shape that "cross-fire" radiation is possible. Half-strength applicators screened with 1/10 mm. of lead should be employed, and the exposure should be from one to three hours' duration, spread over three successive days. Little or no surface reaction is produced by this method of treatment, and the nævus shrinks gradually and steadily. If on palpation the presence of a pulsating vessel is appreciable the case is not likely to prove completely successful unless the vessel be first ligated.

Warts and papillomata.—These all yield readily to short exposures of from 20 minutes to one hour's duration with half-strength apparatus unscreened. The reaction is but slight and the resultant scar scarcely noticeable.

Tuberculosis of glands.—In cases where surgical measures have been declined for cosmetic reasons radium often proves of considerable value, either when used alone or as an adjunct to vaccine treatment. Heavily screened exposures of 30 or more hours' duration should be resorted to and an effort made to secure "cross-fire" irradiation where practicable. If the glands be caseating radium treatment is of but very little use.

Lupus vulgaris.—As a routine treatment for this disease Finsen light is greatly to be preferred to radium, but where the former fails to effect a cure or improvement radium sometimes proves of great use. Unscreened exposures of one or two hours' duration must be given and a destructive reaction produced. The resultant scar is usually firm, smooth, supple, and inconspicuous.

Spring catarrh.—In this condition the employment of radium is strongly to be advocated, as it will often cure the most intractable cases. Personal idiosyncrasy is, however, a very important consideration, and it is essential to proceed with great caution, giving short unscreened exposures at intervals of a fortnight and carefully noting the reaction. If the dosage be accurately adjusted the granulations on the orbital conjunctiva gradually disappear; there is no marked inflammation and no resultant scarring of the mucous membrane. A special form of applicator should be used which can readily be introduced into the conjunctival fornices. It should be of full strength, and the first exposure should not exceed 15 minutes' duration. No screening is employed. If the effect be not satisfactory the length of the exposure may be increased to 20, 25, or 30 minutes until the desired result is obtained.

SKIN DISEASES.

Keloid.—This condition continues to give most excellent results when treated with radium, and a great improvement, if not complete cure, can be safely predicted. In tender and painful keloids the anæsthetic effect of radium is generally very marked, and appears very early in the treatment. Screening with 1 mm. of silver is almost always employed, and an exposure of from 18 to 30 hours spread over from three to five days, according to the size and thickness of the lesion, is given. This brings about a gradual absorption of the keloidal tissue unaccompanied by any surface irritation.

Lupus erythematosus.—This very intractable and puzzling disease often responds favourably to radium, even after all routine methods have failed.

Short exposures with half or quarter strength apparatus lightly screened and repeated at intervals of four weeks give the best results.

Psoriasis and chronic eczema.—Both of these conditions generally yield readily to short unscreened exposures of from two to five minutes' duration, given on three successive days, the series of exposures being repeated at intervals of a fortnight. The patches quickly disappear after a slight superficial reaction, and in eczematous cases there is but little tendency to recurrence. With psoriasis, however, the disease almost invariably reappears after a time, though with some patients the interval that elapses may be of many months' duration.

Lichenification of the skin.—This affection, with its attendant intolerable itching, is quickly relieved and often completely cured by one exposure of 10 or 15 minutes' duration to a half-strength applicator screened with 1/100 mm. of aluminium. Some very obstinate cases which have hitherto defied all the usual methods of treatment have responded most favourably to this procedure; the lesions have disappeared and have not recurred.

Pruritus.—The analgesic effect of radium is often of the greatest use in this disease, and short unscreened exposures frequently produce a degree of relief which is unattainable by any other measures. This is especially noticeable if the pruritus occur in association with a definite lesion such as leucoplakia or hyperkeratosis. If the dosage be carefully considered and the treatment repeated at fortnightly intervals until the skin is restored to its normal condition, complete and permanent cure may result. If, however, the condition be a neurosis the prognosis is not so hopeful and the benefit derived, if any, is not likely to be of very long duration.

GENERAL DISEASES.

Exophthalmic goitre.—Few patients suffering from this disease have as yet been treated at the Institute, but the results obtained are sufficient to justify a trial of radium when other treatments have failed to produce any result. Prolonged exposures of 30 or more hours' duration in all should be given, with heavily screened apparatus containing 200 or 300 mgm. of radium, the apparatus being so disposed as to cover as much as possible of the gland surface. Three or four weeks usually elapse before any effect is appreciable, but from that time on a gradual diminution in the size of the gland, with slowing of the heart's action, lessening of tremor and of the degree of proptosis, may be looked for. The series of exposures should be repeated at intervals of three or four months.

Arthritis deformans.—The daily administration of 250 c.c. of radium emanation solution of a strength of not less than 1 millicurie per litre to patients suffering from this obstinate, painful, and crippling disease is sometimes attended by very remarkable results. It is difficult to predict with certainty as to the degree of improvement likely to occur in any particular instance, but the cases which appear to derive most benefit are those in which the disease is of relatively short duration, and the changes are periarticular in type, and multiarticular in distribution. The age of the patient also exerts some influence, those under 40 responding more quickly to the action of the emanation. Cases with a definite gouty history sometimes experience an acute exacerbation of all their symptoms within the first week or ten days of their treatment, but this disturbance is quite a transient one, and is usually followed by a distinct change for the better. Little or no improvement can be looked for in instances where cartilaginous or osseous changes are predominant, and the radium emanation solution is powerless to bring about the absorption of osteophytic growths or the loosening of fibrous or bony ankylosis. When limitation of movement is due to periarticular fibrous thickening, considerable increase of mobility often follows on the taking of the radium water and enables patients to perform actions such as feeding themselves, brushing their hair, shaving, &c., which they may have been powerless to do for some months or even years.

Other favourable effects of the treatment are the lessening or disappearance of the muscular and articular pains, the grating of the joints on movement is not so marked, the muscles regain much of their lost tone, and the patient's general health is much improved. This is especially noticeable when the patients are suffering from anæmia, their hæmoglobin index being rapidly increased.

Much research work has yet to be undertaken to enable an accurate opinion to be formed of the manner in which radium emanation solution produces these results, as its action appears to be a multiple and highly complex one, but the reinforcing of the body ferments, the increase of tissue oxidation, and the dissolving of uric acid are undoubtedly factors which contribute to its success.

I desire to express my indebtedness to my assistants, Dr. J. E. A. Lynham and Dr. A. Burrows, for the valuable help they have given in the compilation of this report. The opinions recorded are the result of our joint observations, as treatment has in many instances been planned and carried out entirely by them.

APPENDIX.

Report of the Chemico-Physical Laboratory, by W. L. S. ALTON, *F.I.C.* (*Director*).

Since the publication of the last report the laboratory staff has been almost wholly engaged in attending to an ever-increasing demand for emanation applicators and for radio-active water.

Emanation applicators.—These applicators have a very great advantage over applicators containing fixed radium salts, inasmuch as it is possible to concentrate the activity per unit area to a very high degree. Since the emanation in equilibrium with 1 grm. of metallic radium only occupies a volume of 0·59 c.mm., it is easy to see what advantages can be obtained by the saving of space compared with the relatively bulky radium salt. For example, the tubes containing 100 mgm. of radium bromide used in the Institute measure 40 mm. long and 2·2 mm. diameter, while it is quite easy to make an emanation tube equal in activity to them but measuring only 6 mm. long and 1·3 mm. diameter. Improvements in the construction of the apparatus used have resulted in the production of these emanation tubes of very small calibre, the latest achievement being the charging of iridium-pointed platinum needles (3 cm. long, 2 mm. diameter, and 0·3 mm. thickness) with emanation in capillary glass tubes for the insertion into malignant tissue. These needles, the suggestion of the medical staff of the Institute, appear to be easy to use, and if certain principles are observed are not difficult to fill with emanation.

The larger emanation tubes have been standardised in dimensions—that is to say, they have been constructed to fit certain standard screens. These screens are of the following dimensions: an "A" screen is 2 cm. long, a "B" screen 3 cm., and a "C" screen 4 cm., all of them with an internal diameter of 2 mm. The screens vary both as to material (lead or silver) and as to thickness of wall, thus giving considerable latitude in the treatment of special cases.

With the improvement of the apparatus the rate of production of these tubes has enormously increased; two tubes are frequently made at the same time from one piece of capillary tubing, and are separated by means of a mouth blowpipe, a constriction being made in the middle of the tube before the introduction of the gas.

It has been urged against the use of emanation tubes that their initial activity, which is often considerable, is rapidly lost, and that their residual activity, which is small in amount but of long duration, cannot be made use of. The answer to the first point is that a treatment rarely exceeds 24 hours, and that an emanation tube can so be made that its average strength during that period shall be the strength required (the loss during 24 hours being only 16 per cent). As regards the second point, when emanation applicators are returned after use to the laboratory they frequently possess considerable residual activity. As a rule the individual tubes are no longer sufficiently powerful to be of any therapeutic value, but an apparatus has been devised whereby the tubes are crushed and the emanation extracted, several tubes of low activity being utilised to make a tube of high activity.

The stock of radium salts available for emanation production has been subdivided for the sake of safety into units each of about 200 mgm. of radium bromide. Each unit has been attached to its own pump and has been mounted separately on the walls of the iron safes in the basement. All the pumps and glasswork have been made by the laboratory staff, considerable time having been spent in their construction. During the year 241 emanation tubes and applicators have been made (as compared with 44 in 1912), and the activity of these applicators was equal to that of over 19 grm. of radium bromide. These applicators were sent by post as required to various places in the British Isles.

Radio-active water.—The output of radio-active water has also been largely increased during the year, over 3600 litres being made in 1913, as compared with 400 litres in 1912. New apparatus has been constructed which permits of 150 bottles being despatched daily by post to patients as directed by their medical attendants. The strength of the water remains the same as for last year—that is to say, approximately 1 millicurie per litre.[1] The emanation used for the production of this large volume of water is equal in activity to about 6·5 grm. of radium bromide.

Radium applicators.—During the year there has been a considerable demand by medical men and by other institutes for the preparation of radium applicators similar to those used in the Institute. Applicators have been prepared for several of the London hospitals as well as for institutes in Germany and Denmark. The number of these amounts to 55 (as compared with 4 made in 1912). In addition 15 specimens of radio-active material were received from various sources for analysis, a branch of the laboratory work which shows signs of increasing since the acquisition of an International standard.

---

[1] A millicurie of emanation is equivalent to 2,670,000 Maché units.

ROYAL SANITARY INSTITUTE.—The Earl of Plymouth (President) occupied the chair at the dinner of the Royal Sanitary Institute held at the Langham Hotel, London, on May 13th. Amongst those present were Sir Thomas Barlow, President of the Royal College of Physicians of London, Sir Rickman J. Godlee, President of the Royal College of Surgeons of England, Sir Shirley F. Murphy, Professor Sheridan Delépine, Mr. Herbert Jones, Colonel J. Lane Notter, R.A.M.C., Dr. Arthur Newsholme, Surgeon-General Sir Lionel Spencer, Professor H. R. Kenwood, Dr. Louis C. Parkes, Dr. W. J. Howarth, Dr. E. F. Bashford, Professor Bostock Hill, and Mr. A. Wynter Blyth. After the usual loyal toasts had been honoured the toast of "The Royal Sanitary Institute" was proposed by the President, who pointed out that the institute was obtaining support from the most distant parts of the Empire. Sir Henry Tanner, chairman of the council, replied. The health of the visitors was proposed by Mr. H. Percy Boulnois, M.I.C.E., and Sir Thomas Barlow and Principal E. H. Griffiths, F.R.S., of the University College of South Wales and Monmouthshire, responded. The health of the chairman was proposed by Colonel Notter, and Lord Plymouth made suitable acknowledgment.

THE DIAGNOSIS OF PULMONARY TUBERCULOSIS:

THE VALUE OF BESREDKA'S ANTIGEN IN THE COMPLEMENT-FIXATION TEST FOR TUBERCULOUS DISEASE.

By A. C. INMAN, M.A., M.B. OXON.,
SUPERINTENDENT OF THE LABORATORIES OF THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

IN May, 1913, M. Besredka, of the Pasteur Institute, in Paris, asked me to undertake some observations on patients suffering from pulmonary tuberculosis with a view to determining the diagnostic value of the complement-fixation test of the blood in the presence of a tubercle antigen prepared by himself. For this purpose he kindly supplied me with a quantity of antigen which is prepared by growing tubercle bacilli in a liquid medium consisting of veal broth and the white and yellow of the hen's egg. No peptone, glycerine, or salts are employed. After the growth has proceeded for from three to four weeks the culture is heated to 115° C., filtered free from bacteria, and should contain sufficient tuberculin to kill a tuberculous guinea-pig in a dose of 1·5 c.c. to 2 c.c.

The technique employed in the series of experiments referred to in the present communication needs description. In the complement-fixation test the following reagents are required: antigen, control and test human sera, complement, specific hæmolytic amboceptor, the corresponding erythrocytes, and physiological salt solution.

1. *The antigen.*—This was received direct from Paris in hermetically sealed stout-walled test-tubes and placed in the ice safe until required for use. Immediately before each experiment the required amount was decanted into a measuring flask and 1/20 c.c. of a 15 per cent. solution of pure crystallised sodium chloride for every 1 c.c. of antigen was added. The mixture was well shaken and poured into test-tubes. After a series of trials the dose of antigen for each tube was fixed at 0·3 c.c.

2. *The human serum.*—10 c.c. of blood were removed from the median basilic vein by venepuncture. The serum was always inactivated at 55° to 56° C. for 30 minutes. The blood was examined within 48 hours of withdrawal. The dose of serum was fixed at 0·2 c.c. for each tube. In the majority of experiments progressive dilutions of the serum were examined, as will be shown later.

3. *Complement.*—Fresh guinea-pig blood was used. Immediately after withdrawal clotting was allowed to take place in the air incubator at 37° C. for one hour. The clot was then freed from the walls and the tube placed on ice until required for immediate use. A 1 in 30 dilution of the clear serum was used in a dose fixed by titration in the presence of antigen and normal serum. The adequate dose was usually found to be 0·5 c.c. or even 0·4 c.c., rarely 0·6 c.c.

4. *Specific hæmolytic amboceptor.*—A rabbit-sheep hæmolysin was used. This was obtained already standardised from the Sächsisches Serumwerk und Institut für Bakteriotherapie, Dresden, and gave uniformly satisfactory results. The dose used was four to five times the minimal hæmolytic dose.

5. *The test erythrocytes.*—The corpuscles contained in 5 c.c. of fresh whipped sheep's blood were washed at least three times and suspended in 95 c.c. of physiological salt solution. The corpuscles were

sensitised 20 minutes previous to use, and the dose for each tube was fixed at 0·3 c.c.

6. *Physiological salt solution.*—0·85 gramme of pure crystalline sodium chloride was dissolved in 99·15 c.c. freshly distilled water, the solution being newly prepared for each experiment.

The Complement-fixation Text.

A preliminary series of bloods were examined as follows:—The complement 1 in 30 was titrated in the presence of antigen and a known normal serum in doses 0·2, 0·3, 0·4, 0·5, 0·6, 0·7, 0·8 c.c. The hæmolytic dose having been established, four tubes were arranged for each blood and received the reagents as shown in Table I.

TABLE I.

Tube number.	Antigen.	Inactivated serum.	Complement (1 in 30).	0·85% NaCl.	Sensitised sheep's corpuscles.
	c.c.	c.c.	c.c.	c.c.	c.c.
1	0·3	0·2	0·5*	0·3	0·3
2	0·3	0·2	0·6	0·2	0·3
3	0·3	0·2	0·7	0·1	0·3
4	0·3	0·2	0·8	—	0·3
	Contact for one hour at laboratory temperature and one hour 37° C. in air incubator.				
	Contact for half an hour at 37° C. in air incubator.				

* Minimal hæmolytic dose.

The tubes were then placed in the ice safe overnight and the results read off on the following morning. Of 52 sera obtained from patients suffering from pulmonary tuberculosis with tubercle bacilli present in the sputum, 50 cases gave a positive reaction, and 2 cases a negative reaction. At this point I had the advantage of discussing my results with Professor Georges Dreyer, and he advised me to make quantitative examinations of the blood by progressively diluting the serum whilst keeping the other reagents constant. By trial and error the following technique was found to be most suitable for the purpose, and it was thus that the remaining 286 cases referred to in this communication were examined:—

* Dose determined by titration in presence of antigen and known negative serum.

The results obtained may be conveniently given in tabular form. Table III. summarises the findings gained from single examinations in 100 cases of pulmonary tuberculosis, having tubercle bacilli present in the sputum at the time of the blood examination, and chosen at random from the in-patients at the hospital.

Of the five negative cases three were "resting febrile," one "ambulant febrile," and one "ambulant afebrile." In all five cases the duration of the disease was under one year. Subsequent re-examination of these cases gave a positive reaction in four, whilst one of them remained negative.

Table IV. deals with the strength of the reaction in relation to the duration of the disease, and is self-explanatory.

TABLE IV.

Hæmolysis with serum—	Duration of disease.

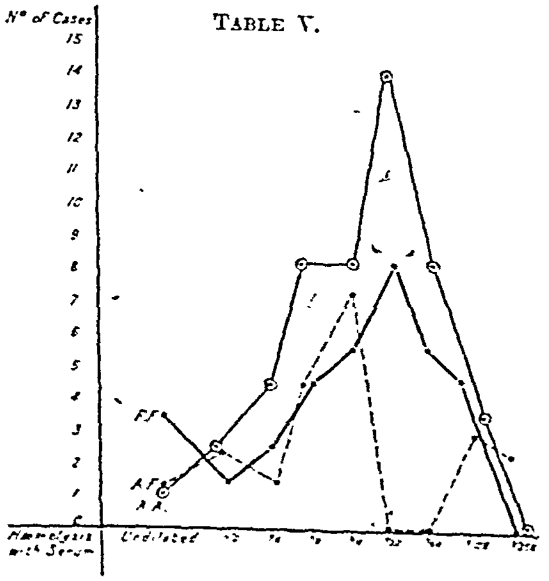
Total	59	28	6	7

Table V. graphically represents the frequency of strong and weak reactions in febrile and afebrile cases. It also is self-explanatory.

TABLE V.



R.F., Resting febrile (32 cases). A.F., Ambulant febrile (20 cases). A.A., Ambulant afebrile (45 cases).

For controls reliance had to be placed on bloods obtained from patients admitted to general hospitals in London suffering from diseases presumably other than tuberculosis. Manifest sources of error creep in here. Firstly, cases admitted for the treatment of traumatic, infective, or neoplastic diseases, or of diseases anatomically defective in origin, are not minutely examined for evidence of tuberculous infection. Secondly, in many of the cases here dealt with a special examination with a view to determining the presence or absence of active tuberculous infection was impossible. Thirdly, tuberculous infection, at all events of a transient nature and of such a degree of activity as only to be detected with difficulty, is common amongst the hospital classes of the population of the country. Such evidence as is to hand tends to show that the number of positive reactions would be considerably diminished were a series of healthy adults drawn from the same social status to act as controls.

TABLE VI.

8.	" " " " 1/128 ...	0	... ...	
		100		

Table VI. gives the results obtained, and is valuable in that it shows that no positive reactions were obtained with a 32-fold dilution of the serum, whilst reference to Table III. shows that nearly one-half of the certainly active cases of pulmonary tuberculosis give a positive reaction with the serum thus diluted.

The composition of the antigen suggested the possibility of a positive reaction being obtained in cases of syphilitic infection. Indeed, this proved to be the case. Samples of serum examined by independent observers at several London hospitals were investigated according to the technique described above, and the following results were obtained:—

TABLE VII.

15 Wassermann negative sera.
1 ... { Complement-fixation test negative in 13
" " positive in 2*

21 Wassermann positive sera.
2 ... { Complement-fixation test negative in 0
" " positive in 21

* The clinical diagnosis was not inquired into in these cases.

It remained, therefore, to determine in how far this necessitates the simultaneous determination of the Wassermann reaction if the test is to be used for diagnostic purposes.

In a series of 158 cases of pulmonary tuberculosis at the Brompton Hospital, excluding those cases with clinical manifestations or a history of syphilis, Captain A. N. Dickson, I.M.S., and myself have found that 8 cases (5 per cent.) gave a positive Wassermann reaction. Strictly speaking, then, the possibility of a positive Wassermann reaction interfering with the correct interpretation of the test must be excluded if the test be applied for the diagnosis of tuberculous infection. In practice, however, it can hardly be gainsaid that such a precaution, at all events in reasonably selected cases, need not be seriously considered so long as the contingency is borne in mind.

Fifty cases were examined because the diagnosis of active tuberculosis was uncertain. It must be understood that the positive diagnosis in these cases may have been probable or improbable; the sole reason for their investigation was the absence of tubercle bacilli from the sputum. Table VIII. summarises the results obtained.

TABLE VIII.

1.	Hæmolysis with serum undiluted...	20	= 40% negative.
2.	" " " diluted 1/2	4	60% positive.
3.	" " " " 1/4	10	
4.	" " " " 1/8	7	
5.	" " " " 1/16	3	
6.	" " " " 1/32	1	
7.	" " " " 1/64	3	
8.	" " " " 1/128	2	

It is suggestive that these figures almost exactly coincide with those obtained in a similar class of case investigated by means of the tuberculo-opsonic index test.

Exercise produces no immediate quantitative effect upon the antihæmolytic power of tuberculous serum as the following experiment shows:—

TABLE IX.

Case.	Hæmolysis with inactivated serum.								Tuberculo-opsonic index.	
	Undiluted.	1/2	1/4	1/8	1/16	1/32	1/64	1/128	Active serum.	Heated serum.
1.—At rest	0	0	+	C	C	C	C	C	0·78	0·16
After 1½ miles' walk	0	0	+	C	C	C	C	C	1·00	0·47
2.—At rest	0	0	0	0	0	+	C	C	0·88	0·32
After 3 miles' walk	0	0	0	0	0	+	C	C	0·63	0·28
3.—At rest	0	0	+	C	C	C	C	C	1·04	0·12
After 1 mile walk	0	0	+	C	C	C	C	C	1·00	0·06

0 = no hæmolysis. + = partial hæmolysis. C = complete hæmolysis.

Conclusions.

1. The antihæmolytic power of tuberculous serum can be made manifest in a hæmolytic experiment by introducing Besredka's antigen into the mixture.

2. Repeated positive reactions, especially with a 32-fold serum dilution, in the absence of a positive Wassermann reaction, indicate the presence of an active tuberculous lesion.

3. Repeated negative reactions indicate the absence of an active tuberculous lesion, if cases of under 12 months' duration be excepted.

A word of thanks is due to those who have helped in the accumulation of material for this research. To those physicians at Brompton Hospital who so unreservedly placed cases under their charge at my disposal, to Dr. Arthur Latham, Dr. J. W. Linnell, Dr. D. Embleton, Dr. A. Paine, Dr. A. Leitch, Mr. E. A. Tozer, Dr. H. A. Treadgold, and Dr. W. P. Johnston I express my gratitude. To Professor Georges Dreyer I owe an especial debt of gratitude for friendly criticism and advice. To M. Besredka I extend my thanks with the wish that his labours in the interest of suffering mankind may meet with the success they deserve.

Brompton Hospital, S.W.

REMARKS ON THE SO-CALLED RE-EDUCATION OF THE DEAF.

BY RICHARD LAKE, F.R.C.S. ENG.,
SURGEON, DISEASES OF THE EAR, SEAMEN'S HOSPITAL, ETC.

FOR many years there have been before the public and the profession various mechanical contrivances which have been recommended for the so-called re-education of the deaf, and also for the education of the congenitally deaf, the contention being that it was possible materially to improve the hearing in those who were suffering from acquired deafness, as one already knew that it was frequently possible to stimulate or educate the hearing of those congenitally deaf. For a considerable time the use of instruments was confined to a few aurists in Paris and Vienna, some of these gentlemen claiming very wonderful results. As was quite natural these claims became known to the British public, and one was constantly finding inquiries directed towards the subject of sound re-education of the deaf by one's patients, and at the same time one not infrequently heard stories of very wonderful recoveries. Within the last few years mechanical engineers of considerable ability, seeing the large amount of money that was to be made by acting as unqualified re-educators of the deaf, produced clever sound-producing instruments and started in the business, and now flood the land with pamphlets, and by all accounts have a very large following. I have seen, I must admit, a large number of people at one time or another who have been to them, but so far I have personally observed no good results from the treatment. And, indeed, as will appear by what I shall say presently, I should have been astonished if I had.

Some years since I purchased an instrument designed for the relief by re-education of the deaf, having been very favourably impressed by the improvement that had been derived by one of my patients from this treatment, an instrument in which the sound-producing force was air; the treatment was carried out by Dr. Marage. I have treated during the last two years for a greater or less time somewhere about 20 cases, with an appallingly small amount of success. It may be that it was because the cases so treated were almost without exception cases which had refused to yield in any way to my ordinary methods of treatment, either cases of advanced progressive middle-ear deafness or otosclerosis, with a few nerve cases. Only one case appeared materially benefited, and that lady was of a very nervous temperament. I have therefore come to the conclusion that in cases of acquired deafness this method of treatment is not to be recommended, and that it rarely offers further hope for those patients whose deafness does not yield to properly and judiciously applied remedies.

There is, however, an obverse of this, and that is the use of mechanical educational methods in the treatment of the congenitally deaf, and it is pleasing to be able to say that at any rate one variety of one re-educational instrument (perhaps others) is of great benefit in stimulating the dormant power of hearing in this class of patient. But it must also be understood from the beginning that the appreciation of sound by the deaf-mute can only be of value when correct instruction is given to the child in the appreciation of sound pitch and so on. Besides the boy whom I showed at the Otological Section of the Royal Society of Medicine on February 20th of this year I have a little girl patient of nearly the same age who has made very marked improvement, though not so great as the boy. At the end of a twelvemonth's intermittent treatment, the former is now able to hear and comprehend most words which are spoken to him in a distinct voice into the concha, whereas the little girl is somewhat behind this, yet her progress is very remarkable. A third case I have treated was a boy very much older, who has just become an apprentice, and who has six weeks' treatment once or twice a year. Everybody has been struck by the great improvement in his vocalisation and hearing.

Another case was that of a young lady, aged 18, a congenital deaf-mute, who commenced to hear a little at about the age of 12, and when she came to me was able to hear a loud voice at about 3 inches from her right ear. I gave her four weeks' treatment at mechanical re-education, and at the end of the four weeks she was able to hear on the right side words spoken in an ordinary voice over 3 feet away. None of these patients had ever been treated with the method of Urbantschitsch, so one is unable to say whether mechanical treatment would succeed where vocal treatment failed.

Educational treatment of the congenitally deaf must be considered from a totally different standpoint from the re-education of the sufferers from acquired deafness. This treatment is rational and by no means new. Itard was, as far as I know, the first to practise education of the congenitally deaf, and since that time very many attempts have been made, both by vocal stimulation of the auditory nerve and by mechanical stimulation, to rouse and bring out, as it were, the dormant power of hearing possessed by many congenitally deaf children and even adults. Urbantschitsch was one of the modern pioneers of these endeavours to ameliorate the condition of these unfortunate people.

One asks oneself how is it that in some instances children born without any sense of hearing have been known to acquire, usually in late childhood, without any artificial nerve stimulus, a certain amount of hearing. The only feasible explanation is that the connecting tract between the nerve centres, and therefore the perception and interpretation of sound, is delayed in its development. Whatever the interpretation may be, there is no doubt that there are analogous instances in at least one or two of the special senses, and there are many minor ones in the auditory nerve, such as tone deafness and inability to copy certain sounds; this is especially marked in the aspirates, which may, and often does, persist through life, but which may entirely be eliminated by tuition.

These cases of delayed auditory perception have been made use of to show miraculous cures by means of these hearing appliances. In the class of case to which I am referring the connexion between the centres is already made, and it only requires a little practice or use to give the recognised acquaintance, both conscious and subconscious, with the altered conditions. But there exists, no doubt, a very large number of people who are born deaf, and who never in the ordinary way develop any hearing power, but in whom it is possible to develop this power if proper steps are taken. In fact, we may classify congenital deaf-mutes under (*a*) those with demonstrable rudimentary power of hearing, and (*b*) those with no apparent hearing. Of these congenital deaf-mutes the first are all potential hearers; the second, however, certainly contain an unknown proportion of non-potential hearers. The class of case in which one can demonstrate a rudimentary power of hearing is relatively small, and the amount of hearing that these persons possess is often restricted to a single note.

The great drawback to educational treatment by means of mechanical appliances is the length of time over which the treatment has to extend and the consequent great expense entailed. For it is quite certain that one must at times be prepared to work for somewhere about three months even if no result is appreciable earlier; the two children under my care, as I have already mentioned, have now had considerably over a year's treatment.

If these congenitally deaf patients do not acquire a sufficient amount of auditory perception and acuity to enable their hearing to be of definite use in daily life, yet it is of immense value as enabling them to acquire a proper or better pronunciation, or one might say an intelligible pronunciation. It enables them to acquire a voice free from the monotone of the ordinary deaf-mute, though it is true this latter has apparently been obtained without the benefit of any auditory perception on the part of the patient. Still, it must be infinitely harder to teach a patient without auditory perception and must take a far greater time.

Briefly summarised, my view with regard to the instrumental re-education of the deaf is that it is almost useless in acquired deafness of adults. It is most useful in congenital deafness, even should this be total, and it is also of value in acquired deafness of childhood when this is not due to any destructive lesion of the internal ear.

Harley-street, W.

A CONTRIBUTION TO THE KNOWLEDGE OF EXPERIMENTAL NEPHRITIS.

BY HORST OERTEL, M.D.

(From the Gordon Pathological Laboratory of Guy's Hospital, London.)

UNTIL quite recently the opinion prevailed that the action of certain poisons on the kidney was selective. It was supposed that some, like cantharidin, injured almost exclusively the vascular system and therefore produced a vascular nephritis; others, like chromium, bichloride of mercury, and uranium nitrate, destroyed the secretory tubular cells, leaving the blood-vessels and glomeruli untouched, and therefore produced tubular nephritis. It became, then, common to differentiate between vascular and tubular nephritis as rather distinct affections, and this in spite of well-founded evidence to the contrary.

In 1904 Lyon, in an important contribution[1] which has not received the general recognition and appreciation it deserved, showed clearly from his own experiments and the investigations of others that in cantharidin poisoning there occur not only vascular injury and reaction, but a diffuse necrosis of the secretory tubular cells, and that in poisoning by bichloride of mercury glomerular lesions may also be present. Similar results have been obtained by subsequent investigators for these and still other types of experimental nephritis. Thus Pearce, for example, found the evidences of tubular injury and reaction in cantharidin nephritis,[2] and Christian and O'Hare[3] have described various glomerular lesions in uranium nephritis. I have further emphasised on various occasions that, as far as the human kidney is concerned, a distinction between vascular glomerulo-nephritis and tubular nephritis is not justifiable.[4]

While these investigations have considerably modified the former conception of a strict division between vascular and tubular nephritis, the idea still remains that in some types of nephritis the involvement of one or the other renal structure is greater, and therefore dominates in the effects on resulting functional disturbances. There is hardly any other idea which is more indiscriminately used and has done so much harm in the formation of correct pathological conceptions. For it is in fact extremely unsafe to judge the severity of functional disturbances by the relative ease with which morphological changes may be detected, or to use mere quantitative measures as an absolute index of functional disturbances. Pearce and Eisenbrey,[5] for example, demonstrated that nephrotoxic and hæmolytic immune sera cause changes which by physiological methods present no evidences of vascular injury, but which are anatomically characterised by exudative glomerular lesions of moderate severity. In arsenic poisoning, on the other hand, physiological methods show profound vascular changes, but the anatomical investigation shows little or no vascular lesion. A simple observation will further convince one in that respect: cantharidin produces morphologically an impressive exudative nephritis with an abundant emigration of leucocytes, diapedesis of red cells, and frequent hæmorrhages; uranium nitrate, on the other hand, produces usually only serous exudation, no emigration of leucocytes, and rarely small and limited hæmorrhages. Still in these, apparently milder, less severe vascular lesions the amount of serum albumin (coagulable by heat) in the urine is as great as, sometimes greater than, in the apparently more severe cantharidin nephritis. The injury to the vessels in uranium nephritis, therefore, must be quite pronounced. This is borne out by a careful morphological investigation, for, while an impressive emigration of leucocytes is absent, we find an unusually large quantity of serous exudate. We are dealing in such cases with still unknown qualitative disturbances which are, although more difficult of detection, of importance in altering the constitution of tissues.

Indeed, Aschoff's and Suzuki's[6] extensive work has shown in regard to the secretory tubular cells that the character of degeneration differs for various poisons, and that these differences may have an effect on accompanying functional changes. They deserve, therefore, a closer study than has until now been accorded to them. Aschoff and Suzuki find that, for example, uranium and mercury produce necrosis of cells associated with a dropsical hyaline degeneration; cantharidin, on the other hand, necrosis with marked swelling and vacuolisation of the cells. They come to the conclusion that *all* poisons act primarily on the parenchyma—that is, the different parts of the convoluted tubules; and further, that the differences in functional disturbances, which have lately been the source of much experimentation and discussion, must rather be attributed to individual differences and complexity in the topographical action of poisons and their varying effects on blood pressure, and not to injury of specific kidney constituents.

Without going into a full discussion of this matter again, I may add that I have recently been able in the course of some experiments to convince myself that, at least as far as cantharidin, chromium, bichloride of mercury, and uranium nitrate are concerned, there occurs primarily parenchymatous degeneration of the tubular cells which is most marked in the convoluted portions. In cantharidin nephritis particularly this is, even with small and moderate doses, extremely severe, leading to early necrosis of these cells, even before an exudation in glomeruli is visible. For this reason the fatty changes in cantharidin poisoning are probably less conspicuous than after bichloride of mercury and, under certain conditions, in uranium nitrate, in which the parenchymatous destruction appears to proceed less violently.

It should further be noted that these kidney poisons involve early the vascular system in an exudative process. In chromium, mercury, and uranium nephritis this is mainly of a serous character, while in cantharidin it is associated with marked emigration of leucocytes. These are constant results, but others may at times be noted, such as hyaline thrombi or hæmorrhages in the glomeruli and hæmorrhages in the tubules. A noticeable output of serum albumin and the formation of casts are therefore features of all cases of experimental nephritis. Differences in these results are individual rather than specific. There is, however, still another important complication of experimental nephritis that undoubtedly enters into the functional changes which have been observed by various investigators and which have been interpreted by some as an index of the type of renal injury—namely, the results of metabolic disturbances which follow the general effects of poisons on the organism. For it is evident that functional disturbances of renal activity may not only arise within but outside of the kidney. This consideration has until quite lately been disregarded, and we know very little about the changes which these poisons produce in other organs, notably the liver, which as the largest metabolic gland demands first importance.

In a recent contribution Opie[7] has offered some interesting information in this respect. His attention was attracted by the occurrence of œdema of the liver and gall-bladder in cantharidin nephritis, which suggested to him the possibility that changes in the liver may have a part in the functional disturbances which accompany this nephritis. His investigations showed that cantharidin exerts a decided influence on the lymph flow of the liver which is associated with definite structural changes. In observing these changes for several hours after the administration of cantharidin, he found at first a short period of retardation of lymph flow from the liver, later, however, a decided rise. Macroscopically the liver became turgid, homogeneously deep red, without lobular markings, and blood escaped in great abundance from the cut surfaces. Microscopically such livers showed an accumulation of lymph containing red blood cells in the dilated lymph vessels. Similar pictures were presented by the regional lymph glands, which also showed the presence of polymorphonuclear leucocytes.

I have lately carried on an investigation into the structural changes which cantharidin, bichloride of mercury, and uranium nitrate produce in the liver of rabbits. Fifteen animals were employed. Of these 7 were poisoned with varying doses of cantharidin of a strength usually employed in the study of experimental nephritis, 4 were in similar fashion poisoned with bichloride of mercury, and 4 with uranium nitrate. The changes were noted at various times after administration, as seen by the following tabulation, which is arranged according to dosage and length of time the animals lived after poisoning. It should be emphasised that these investigations were not conducted to determine the poisonous properties of definite doses of the respective drugs *per se*, but rather whether doses usually employed and sufficient for the production of nephritis had any effect on the liver. In all cases the presence and the features of nephritis were therefore noted and compared with the liver lesions.

Cantharidin.

Rabbit 1; 2050 grm. Dec. 11th, 1913, ¼ c.c. of 1 per cent. cantharidin in acetic ether at 11.45 A.M. Killed at 4.45 P.M.

Rabbit 2; 2020 grm. Nov. 24th, 1913, ¼ c.c. of 1 per cent. cantharidin in acetic ether at 3.15 P.M. *Died during night.*

Rabbit 3; 1700 grm. Dec. 11th, 1913, ½ c.c. of 1 per cent. cantharidin in acetic ether at 11.45 A.M. Died during night.

Rabbit 4; 2520 grm. Nov. 24th, 1913, ½ c.c. of 1 per cent. cantharidin in acetic ether at 3.15 P.M. Lived to the morning of Nov. 28th.

Rabbit 5; 1470 grm. Nov. 18th, 1913, ½ c.c. of 1 per cent. cantharidin in acetic ether at 2.40 P.M. Died during night.

Rabbit 6; 2070 grm. Ditto (as No. 5).

Rabbit 7; 2000 grm. Feb. 10th, 1914, ½ c.c. of 1 per cent. cantharidin in acetic ether at 3 P.M. Died during night.

Mercury.

Rabbit 8; 1820 grm. Jan. 21st, 1914, 1 c.c. of 1 per cent. mercuric bichloride at 2.45 P.M. Killed on Jan. 22nd at 9 A.M.

Rabbit 9; 1950 grm. Jan. 12th, 1914, 1 c.c. of 1 per cent. mercuric bichloride at 2.45 P.M.; repeated on Jan. 13th at 2.40 P.M. Killed on Jan. 14th at 1 P.M.

Rabbit 10; 1850 grm. Jan. 12th, 1914, 1 c.c. of 1 per cent. mercuric bichloride at 2.45 P.M.; repeated on Jan. 13th at 2.40 P.M. Killed on Feb. 9th at 5 P.M.

Rabbit 11; 1870 grm. Jan. 21st, 1914, 1 c.c. of 1 per cent. mercuric bichloride at 2 45 P.M. Jan. 22nd 2 c.c. of mercuric bichloride at 2.30 P.M. Repeated on Jan. 23rd at 2.30 P.M. Died during the night following Jan. 24th.

Uranium.

Rabbit 12; 1270 grm. Feb. 23rd, 1914, 1 c.c. of 2 per cent. solution of uranium nitrate at 3 P.M. Killed on Feb. 24th at 3 P.M.

Rabbit 13; 1900 grm. Feb. 10th, 1914, 1 c.c. of 2 per cent. solution of uranium nitrate at 3 P.M. Repeated on Feb. 11th at 3 P.M. Killed on Feb. 12th.

Rabbit 14; 1420 grm. Ditto (as No. 13).

Rabbit 15; 3070 grm. March 25th, 1914, 2 c.c. of 2 per cent. uranium nitrate at 3.30 P.M. March 26th 3 P.M. 2 c.c. of uranium nitrate. Killed on March 27th at 3 P.M.

Cantharidin.

The investigations into the effects of cantharidin on the liver showed, in conformity with the observations of Opie, primarily a massive hæmorrhagic congestion and œdema of the liver which at the time when my observations commenced (five hours after administration) had already proceeded to exudation of leucocytes and were associated with marked parenchymatous destruction of liver cells. It is evident, therefore, that the œdema which Opie observed was inflammatory œdema, a view which is also supported by the admixture of red cells to the œdematous fluid in his cases and the presence of polymorphonuclear leucocytes in the similarly affected regional lymph glands. In all my cases there existed from the start marked engorgement of portal vessels with red blood cells and leucocytes. A similar engorgement occurred early in the central veins and the intralobular capillaries. Distinctly eosinophile leucocytes (which always predominate in the rabbit) were scattered through the lobules.

In animals which survived a somewhat longer time, say through part of the night following the afternoon of the injection, these features had become accentuated, advanced, and certain other phenomena had appeared. The liver cells were actively proliferating, showed frequent mitosis, and many of the portal vessels were plugged by inflammatory thrombi. This led to peculiar pictures in some of the adjoining peripheral parts of lobules. Proliferating liver cells had been dislocated, isolated, and, mixing with inflammatory cells, formed rather independent, more or less sharply defined cell foci. Within such foci vessels and bile ducts were seen whose lining cells with their nuclei had fused to form giant cells. Destruction of liver cells throughout was severe and rapid. A large-drop fat infiltration was practically absent, but very fine fat droplets appeared within the protoplasm of disintegrating liver cells.

In one rabbit, which lived for about four days after poisoning, the lesion had undergone some recessions, so that its distribution through the liver appeared somewhat irregular, more localised, and less active. The swelling of the cloudy liver cells appeared generally greater, and was more conspicuous on account of lesser intralobular capillary engorgement. This allowed a better preservation of liver cell columns. Invasion of the lobules by leucocytes was very slight, in many fields absent, even near the portal spaces, so that throughout parenchymatous changes predominated. The nuclei of the liver cells were pale and large, and frequent amitotic and mitotic division occurred.

Mercury.

Schlayer and Hedinger employed a 1 per cent. solution of bichloride of mercury for the production of nephritis, which was administered in doses of ½ c.c. to 1 c.c. and repeated in 14, 19, and 55 hours. The susceptibility of rabbits to mercury is much less than to cantharidin, so that they survive even larger doses better than small doses of cantharidin.

The lesions produced in the liver by bichloride of mercury in a moderate small single dose—say 1 c.c. of a 1 per cent. solution—are after a period of about 18 hours pronounced but irregular parenchymatous degeneration with granular disintegration of the protoplasm most marked around the central vein. Associated is a prominent and diffuse large-drop fat infiltration. This fat is situated not so much in the cells as between them in the lymph and capillary spaces, which show a moderate and irregular but quite evident dilatation, which is also most conspicuous in the centre of the lobules. The disintegrating liver cells contain small fat drops within their degenerating protoplasm. The peripheral cells of the lobules are better preserved, although more or less swollen and cloudy. The portal spaces are intact except for engorgement of their blood vessels. Emigration of leucocytes is absent.

The changes after repeated moderate doses are somewhat more accentuated and modified. Parenchymatous swelling becomes more diffuse, and an œdematous imbibition and dissolution of the liver cells become pronounced, these changes being most advanced in the centre of the lobule. Such necrotic parts are therefore separated by better preserved areas. Fat is found in diffuse distribution, mostly in the form of large fat drops in the necrosing foci, but also in the connective tissue of the portal spaces.

Nuclei of liver cells are to a great extent in various stages of solution, but an abundance of deeply staining, richly chromatic, large nuclei are also seen, which impress one as of very recent origin. Dilatation of capillary vessels remains prominent in the central portions of the lobules and is most conspicuous in the necrosing areas.

On the whole the lesion is dominated, as will have been seen, by the impressive parenchymatous changes with œdema. Leucocytes are absent or present in insignificant number in the affected parts.

Finally, after repeated larger doses (1 c.c. of 1 per cent. bichloride of mercury, followed the next day by 2 c.c., and the day after by another 2 c.c.) one finds a generally quite marked necrotic dissolution of the central lobular cells around dilated central veins. The surrounding peripheral cells are swollen, cloudy, and fatty. Fat in the cells is visible in the form of fine, small drops, but fat is also carried by the larger portal vessels which not infrequently are the seat of hyaline thrombi. Such fat is carried along in the intralobular capillaries and is seen in intercellular spaces in form of small granules.

One of the rabbits after receiving two doses of 1 c.c. of 1 per cent. mercuric bichloride in an interval of one day was allowed to recover from the acute symptoms of the poisoning and to live for about a month. During that time the at first pronounced albuminuria gradually diminished to a faint trace, but the amount of urine became more concentrated and darker coloured. (Bile could not be demonstrated in it.) The animal, however, after a week began to lose weight very rapidly, although it continued to eat quite well. It lost thus from 1850 grm. to 1050 grm. in a month. At that time it was much emaciated and very weak, and was therefore killed.

The changes in the kidney bore a resemblance to those found in continued degenerative nephritis in man. The degeneration of the tubular cells was marked and general but not very violent, and seemed to consist to a great extent in an œdematous swelling associated with fatty changes. The latter were particularly marked in the straight and collecting tubules. These also contained a good number of hyaline casts. The nuclei of the lining cells were relatively well preserved but generally pale, and in the convoluted tubules poor in chromatin and often dissolving. The glomeruli were engorged, plump, œdematous, and the capillary loops individually obscured and adherent to each other, but not to the capsule. There remained, however, only a narrow capsular space as the glomeruli occupied most of it. Cell infiltration or increase was universally absent; neither glomeruli nor periglomerular nor intertubular tissue were increased in thickness or showed an appreciable number of new cells. The whole picture was then controlled by an apparently chronic œdematous imbibition and slow disintegration of parenchyma cells associated with fatty changes and œdema of the glomeruli.

The liver presented also a general swelling and œdematous solution of its cells, which was most pronounced around the engorged and dilated central veins, some of which contained hyaline thrombi. In advanced places this had proceeded to necrosis of liver cells. The arrangement into columns had thus been lost, but the liver cells were for the most part tightly packed without a definite arrangement. Only where a more extensive solution had taken place dilated and engorged capillaries were seen. The peripheral portions of the lobules were better preserved, but the vessels of the interlobular spaces were engorged and the portal connective tissue showed œdematous swelling and turbidity. Cell infiltration or connective-tissue proliferation was absent, but there existed a rather diffuse small-drop fat infiltration mostly visible at the periphery of cells and, where intercellular spaces were visible, between them.

Uranium.

The changes in the liver after administration of uranium bear superficially a closer resemblance to those of mercury than to those produced by cantharidin, inasmuch as parenchymatous degenerations and a serous, not cellular, exudate dominate the picture. There exist, however, certain characteristic differences. In the liver, as in the kidney, the serous exudate is very abundant, so that the inflammatory œdema of the tissues is marked throughout. Consequently the œdematous swelling of the liver cells with subsequent cytolysis is pronounced and complete. These characteristics are noticeable even after relatively small doses (1 c.c. of a 2 per cent. solution). While in mercury poisoning the liver cells show generally prominent fatty degeneration and granular disintegration, uranium seems to produce a simpler œdematous dissolution of cells. Indeed, after larger doses fatty changes, which are present after small or moderate doses, become inconspicuous, probably on account of a more rapid solution of cells, and the enormously swollen, pale cells actually compress the intercellular blood and lymph vessels. They are aided in this by the inflammatory œdema, and in hardened sections coagulated lymph can sometimes be seen between cells. Under such conditions only narrow, short, thin streaks of fat are visible between necrosing cells. Proliferation of liver cells is, probably for the same reasons, practically absent. The central veins are dilated, filled with blood and at times with hyaline thrombi. Their walls are swollen and hazy. Lobular necrosis is most marked around them. Irregular capillary dilatation is present, more especially in wasted areas in which only necrotic cells remain.

Summary of Results.

It is evident from these experiments that definite lesions result in the liver after the administration of cantharidin, bichloride of mercury, and uranium nitrate. These bear a more or less close resemblance to the changes in the kidney. Shortly summarised, cantharidin produces a rapidly progressing and general parenchymatous degeneration, and necrosis associated almost from the beginning with tremendous hæmorrhagic vascular engorgement and cellular exudation. These lead, even in small and moderate doses, to a marked and rapid disorganisation of the liver. The accompanying constitutional symptoms are severe and lead to speedy death.

In mercury the picture is controlled by parenchymatous and fatty degenerations with which œdematous swelling is associated. These lead, according to dose and susceptibility of the animal, to rapid or retarded solution of the cell, especially in the central parts of the lobules. Somewhat similar to mercury are the changes brought about by uranium, but a much greater inflammatory œdema or serous exudate and a greater swelling, vacuolisation, and cytolysis of the parenchyma in kidney and liver distinguish it from mercury poisoning. The fatty changes are less marked than after mercury, due, in all probability, to the greater and more rapid œdematous dissolution of the cells. But in both lesions the central parts of the lobules are most severely involved.

The conclusion may therefore be drawn that cantharidin, mercury, and uranium are not selective poisons, that they affect not only the kidney but the liver, and that they involve in both organs parenchyma as well as circulatory system. Functional changes which have been observed in those instances cannot therefore be regarded as solely due to injury of one or the other part of the kidney, in fact not to the kidney alone, for the alterations in the liver make it probable that these changes are, at least partly, dependent upon metabolic disturbance by these poisons.

Pathological Changes in Liver of Untreated Rabbits.

Before closing, I may be allowed to add a few remarks about certain pathological changes which are frequently found in untreated rabbits, and which at times may become confusing in the investigations of experimental lesions. I will disregard the various parasitic diseases to which the rabbit is liable, because these are most always easy of interpretation. Of others, however, early or later evidences of portal sclerosis which must be the results of frequent vascular or bile duct infections may, particularly when recent and cellular, become a source of trouble in the study of experimental inflammatory changes in the liver. But these are practically always restricted to the periphery of the lobes in close continuity with the portal or bile-duct system and irregularly streaky in distribution.

In this connexion it must also be remembered that the majority of rabbit's leucocytes are, as pointed out by Price-Jones,[8] acidophile, so that the appearance of eosinophile leucocytes is no criterion of the recency of an inflammatory exudate as in man and some other animals. The liver of the rabbit presents, further, not uncommonly small granulomatous formations or pseudo-tubercles. However, most important and misleading are certain changes in the liver cells which occur in connexion with regenerative activities during recovery from spontaneous inflammatory or traumatic liver injury. Under such conditions appear closely packed clear cells without columnar arrangement, usually smaller than normal liver cells, but generally uniform in size. They resemble the lining cells of the collecting tubules in the kidney. Their nuclei are as a rule well preserved, appear at a glance in greater than normal number, and are, depending upon the stage and rapidity of regeneration, in various states of chromatin contents. Many are very rich in, and plump with, chromatin; intermingled with these are others poor in chromatin and even pale. It is not possible to decide whether these latter cells are very early forms of recovering cells, or new cells which gradually are lost during over-production of regeneration. They show sometimes a faint protoplasm. These cells might easily be taken for evidences of a more or less diffuse pathological cytolysis; they differ, however, from this, not only in a much more even distribution and regularity in their morphological appearance, the evident increase in number, their new arrangement, and the greater chromatin contents in many nuclei, but also in the absence of the characteristic irregular, sometimes tremendous, swelling with œdematous imbibition of the cells and the distinct evidences of progressing cytolysis to necrosis which, leaving only a hazy, swollen reticulum, allows a gradual prominence and engorgement of intercellular capillaries with ultimate hæmorrhagic extravasation.

Care must therefore be exercised not to confound, on the one hand, the results of idiopathic infections with the results of experimental procedures, and, on the other hand, the evidences of liver regeneration, occasionally encountered in untreated rabbits, with normal conditions or related to normal liver function.

Many of these pictures were at first very confusing to me, and I owe their better understanding and knowledge to the opportunity offered to me by Dr. Gordon Goodhart, who allowed me a free study of his instructive collection of normal and abnormal rabbits' livers, notably those following trauma or ablation of part of the liver. I must also acknowledge my indebtedness to Dr. P. P. Laidlaw and Dr. R. A. Chisolm *for many acts of kindness. To the latter I owe specimens for the study of chromium* nephritis.

OBSERVATIONS ON SYPHILIS OF THE CENTRAL NERVOUS SYSTEM, WITH A NOTE ON SALVARSAN.[1]

BY J. E. R. McDONAGH, F.R.C.S. ENG.,
SURGEON TO THE LONDON LOCK HOSPITAL, ETC.

FOR convenience in dealing with lesions of the central nervous system the body will be considered as consisting of two divisions: (*a*) that part which is bathed by blood—i.e., the systemic division; (*b*) that part which is bathed by cerebro-spinal fluid—i.e., the nervous division. The distinction is necessary, since there is practically no connexion between the blood and the cerebro-spinal fluid, so that sterilisation of the former may still leave the latter affected. Complete sterilisation of the body will naturally include both the systemic and nervous parts. This point is illustrated by the *following case:—*

A boy, aged 17, contracted syphilis in October, and came under care the following January, being covered from head to foot with a diffuse papulo-erythematous eruption. After eight weekly intravenous injections of neosalvarsan the Wassermann reaction became negative; then mercurial injections were carried on until April. Three weeks after treatment was stopped the patient began to complain of headache, insomnia, and loss of appetite. These symptoms became gradually worse, and he came up for advice again in June, by which time he had lost 2½ st. in weight. The boy looked pale and emaciated, the pupils were slightly unequal, and the reflexes were on the plus side, and there was a general hyperæsthesia, otherwise nothing abnormal was discovered; the Wassermann reaction was negative. Fearing cerebro-spinal syphilis, a lumbar puncture was performed with the following result: Cells, 450 per cubic millimetre; 68 per cent. lymphocytes; 27 per cent. endothelial cells; 5 per cent. *polymorphonuclears.* Nonne-Apelt reaction positive. (This reaction involves the presence of globulin.) Wassermann reaction positive in all dilutions—i.e., from 10 per cent. to 500 per cent. (10% = 1/10 c.c. of a 1 in 10 dilution).

The early onset of cerebro-spinal syphilis makes this case interesting, since few books point out that cerebro-spinal syphilis may occur a few months after infection. I have seen four cases, one of which developed nervous symptoms four months after the chancre was first noticed, no treatment having been received. The other three cases I took to be cured by salvarsan and mercury. Herein also lies the explanation of some of the reported cases of reinfection. Any area of the system can be shut off like the central nervous system, with the result that when the other areas are sterilised the spores in the single area can develop and give rise to a fresh chancre, which is followed in time by the usual secondary symptoms, but such an instance is not a true case of reinfection.

The suggestion at once offers itself that sterilisation of the blood may hasten an attack of cerebro-spinal syphilis owing to a diminution of antibodies. This is, however, far from being the chief point to be learned from such cases. The nervous part of the body can be reached by the infective agent as easily as the systemic, and symptoms of an affection of the former may occur in spite of treatment. The former point is still further emphasised by the fact that the examination of the cerebro-spinal fluid of several early cases of syphilis showed pathological changes; in fact, a lymphocytosis may be obtained in the cerebro-spinal fluid before the Wassermann's reaction in the blood is positive. The cerebro-spinal fluid of latent cases was also examined, and that from cases which had been well treated and *in which the* Wassermann reaction in the *blood* was negative; *pathological changes* were *found*, although no suggestion of the disease manifested itself clinically.

It is very seldom that treatment given by the skin, *muscle*, or *vein* can effect a complete cure in a case of cerebro-spinal syphilis, tabes, or general paralysis of the insane, since the diseased area does not receive a sufficient dose of the drug prescribed. Homer Swift and Ellis[2] have obtained many good results by injecting intraspinously serum rich in antibody, *but* it is feared the treatment is *only* palliative, and several injections are necessary to obtain a satisfactory result. The patient is first given an intravenous injection of salvarsan or neosal*varsan*, and an hour later blood is withdrawn. The *following* day, after the serum has separated off, it is collected, mixed with an equal quantity of distilled water or saline (about 25 c.c. of each), and after a corresponding *amount of cerebro-spinal* fluid has been withdrawn the diluted serum is injected into the canal and the patient placed with his head low *down* and the bottom of the bed raised *so* as to allow the fluid *to gravitate towards* the brain. The best needles for performing lumbar puncture are Barker's, and Messrs. Maw, Son and Sons, the *makers*, have constructed a mount *for my* three-way syringe which makes the injection a simple matter. My best results have been in cases of cerebro-spinal syphilis, in which the improvement has been remarkable, but as a rule *about* eight injections given at weekly intervals are necessary before the cerebro-spinal fluid approaches the *normal*. In some cases, especially in the parenchymatous lesions, the globulin and Wassermann reaction never completely disappear. Some cases of tabes have markedly improved, pupil reflexes returned, crises disappeared, gait become steadier; but so much depends upon the stage the patient is in when treated. On the other hand, some of my cases have remained unaltered and a few have been made worse. I know of two cases in which death resulted. Two cases of general paralysis of the insane which I injected were undoubtedly made worse. Three other cases improved but only to a slight extent.

---

[1] Part of a lecture given to post-graduates at the *London Lock* Hospital, April 17th, 1914.

[2] Journal of the American Medical Association, May, 1913, p. 1577.

Clinically, we draw a very sharp line between cerebro-spinal syphilis, tabes, and general paralysis of the insane. So sharp is it that we may fail to see the common foundation upon which the three are built. The three conditions are not only extremely closely related but may merge into one another, and which is going to crop up will depend largely upon the treatment that has gone before. If sufficient salvarsan to cure the symptoms be given to a patient during the stage of general infection, but not to sterilise the system, and if a recurrence appear, it may be generalised and indistinguishable from the original trouble. The action of the drug is sudden; on the basis of the life-cycle, as described by me,[3] it may be considered that the gametes which are responsible for the symptoms are killed; the body has no further need to form antibodies, and all is well. The spores remain *in situ* and, having no antibodies to disturb them, resume their cycle and give rise to new gametes in exactly the same situations in which they were stunned.

Under the influence of mercury—the action of which is insidious, and not powerful enough to destroy the gametes as previously described, or to give the host its stimulus for the formation of antibodies—the spores to some extent become crippled, extend peripherally to find fresh soil, and if they subsequently multiply they can give rise to a sufficient number of gametes. The lesions will be fewer, more localised, and in the form of circles or segments of circles. Later, owing to the presence of the spores, the vessels become inflamed. This leads to narrowing of the lumen, diminution of the blood-supply to the part, consequent necrosis, and so a gumma.

During the stage of general infection the nervous system is not spared, and that part of it which is fed by blood—namely, the meninges and blood-vessels, becomes infested with organisms. Sterilisation of the systemic part does not sterilise the meninges, as shown by the case to which I have just referred. There are no antibodies except in the cerebro-spinal fluid—a fact which would appear to be for the benefit of the nerve tissue rather than of the meninges—with the result that a generalised meningitis ensues. The cases of cerebro-spinal syphilis seem to me to be relatively increasing. This, if a fact, is explained on the hypothesis that, owing to the feebler action of the antibodies in the cerebro-spinal fluid compared with that of those in the blood, there is nothing to prevent the extension of the parasites from the meninges into the nerve tissue; and this is more likely to occur where they come most closely in contact—viz., brain and cord.

The former results in general paralysis of the insane, the latter in tabes. Most of the blood-vessels extend into the cord from the meninges along the septum posticum, with the result that the posterior part of the cord is better supplied with blood than the anterior part, and as the syphilitic organisms extend along the paths of the vessels it becomes clear how tabes arises. The vessels to the anterior part of the cord do not run along any septum, and therefore have no close connexion with the meninges. A syphilitic lesion of the anterior part of the cord is a vascular one, and is analogous to the early endarteritis of the basilar artery and its branches in the cranium. This makes transverse myelitis and early syphilitic hemiplegia similar pathological conditions. General paralysis is brought about by a spread of the organisms from the meninges into the cortex of the brain, which brings it into the same pathological condition as tabes. This I have been able to prove by finding the phases of the leucocytozoon syphilidis in both the pia mater and brain substance in nine of the ten cases so far examined. Pure endarteritic lesions, if treated early, are cured, the patient recovers without a trace of what has happened, and the condition does not tend to recur. Pure nerve lesions, such as tabes and general paralysis, are not cured, i.e., broadly speaking, since spontaneous cure in tabes is certainly possible. Should the organisms spread in the nervous part, but be crippled in the way described in the systemic part (as occurs under treatment by mercury), localised symptoms prevail; the cerebro-spinal syphilis will become divided, with the appearance of two separate types—the pure cerebral type and the pure spinal type. Further, when the extension of the organisms has become greater and the vascular disturbance more marked, tabes and general paralysis of the insane will follow, and appear late in the course of the disease when the production of the systemic antibodies is checked. I have observed cases which gave persistently negative Wassermann reactions develop parasyphilis, and only when symptoms showed themselves did the Wassermann reaction become positive.

If adequate treatment is begun before the nervous system is attacked it will presumably always remain free. If treatment is begun after the nervous system has been attacked and the treatment is sufficiently powerful early in the disease to stop the host producing antibodies, symptoms of the nervous system, should they arise, will be those of cerebro-spinal meningitis. If the production of antibodies be not stopped till late in the disease, tabes and general paralysis of the insane will ensue. Therefore, if treatment be begun in the secondary stage with mercury alone, or with one or two injections of salvarsan, the patient will run greater risks of getting tabes and general paralysis of the insane. Both these conditions are, in my opinion, steadily on the increase. If, on the other hand, several injections of salvarsan be given and supplemented with mercury, cerebro-spinal syphilis is more likely to result. The patient should be put under treatment before the nervous system is attacked, since, although the pathological changes in the cerebro-spinal fluid may be made to disappear by treatment, sooner or later they all come back again. As to whether this is true after the intraspinal injections of salvarsanised sera, only the future will show.

The moral of all this is to diagnose a sore at once and to put the patient under the most adequate treatment possible—that is, treatment which may be expected to cure the disease completely.

---

[3] Proceedings of the Section of Pathology of the Royal Society of Medicine, [illegible] THE LANCET, [illegible] [illegible]

The nervous system may be affected in other ways, but space forbids their mention here.

Treatment by Salvarsan.

In discussing the action of salvarsan reference will be made to the preparation which is now supplied, since it is considerably feebler in its action than the drug which was first used. The majority of the cases of primary syphilis to which one injection was given over three years ago are now both clinically and serologically sound. The majority of the cases of primary syphilis to which two injections of salvarsan were given when the drug came upon the market have developed symptoms since. Of those which were already in the stage of general infection nearly all showed recurrences within a year, and many within three months. It is only since the rule has been followed to give as many injections as are necessary to procure a negative Wassermann reaction in the blood taken between the seventeenth and forty-eighth hour after the last injection, and to prescribe a year's treatment with mercury, that the fewest recurrences have been observed. Probably in a few more years many of those which have *not* so far recurred will develop symptoms, but until our knowledge increases this procedure is the best. Unfortunately, the Wassermann reaction cannot be relied upon to tell us when a patient is cured because a positive reaction is not necessarily indicative of the disease being active.

In the primary stage, provided that sufficient injections of "606" are given to procure a negative Wassermann reaction in the blood withdrawn within the limits above specified, and that this treatment is further augmented by 24–48 intramuscular injections of mercury, given in 3–6 courses of eight weekly, within the 12–24 months, in the light of our present knowledge a cure is possible. In the secondary stage a cure may possibly be obtained.

Success for the same treatment in the latent stage of the disease and in the stage of early recurrences is improbable, while in the stage of late gummata, nervous syphilis, &c., a cure is impossible—i.e., broadly speaking, since a spontaneous cure may occur at almost any stage. In the primary stage three to five injections and in the secondary stage six to nine injections are required. In late cases even 15 or more injections of salvarsan may fail to procure a negative Wassermann reaction, and supposing a negative Wassermann reaction be obtained it is not long before it becomes positive again. In late cases it appears wiser to give two or three injections of salvarsan to heal the symptoms, and to augment it with a course or two of mercury and iodides, meanwhile informing the patient that he should place himself under treatment again the moment symptoms reappear. Such a patient may go for years without a recurrence, and, should symptoms reappear, they will almost certainly do so at the site of the previous recurrence.

It is universally agreed that the best way to give salvarsan is intravenously, and my own opinion is that the requisite number of injections should follow upon one another at intervals of not longer than eight days; if possible they should be given every four days. It has been frequently noticed that those cases which recurred to which *only two* injections had been given, with or without supplemental mercurial treatment, were never cured, if the subsequent treatment with salvarsan was given in courses of two.

I had two early cases of syphilis in which each patient received in all more than 16 injections of salvarsan, given in pairs and threes with a course of mercury after each, who, after an interval of three months or more, according to the time at which the symptoms reappeared, were in much the same condition in the end as they were before treatment was started—a point in favour of the view that the spasmodic administration of salvarsan greatly lessens its therapeutic action. A most important point to remember in salvarsan treatment is that if too few injections are given to a patient with infectious symptoms, should the symptoms recur, they will simulate those for which the drug was prescribed. Several cases have been seen of patients who had condylomata, for instance, which disappeared under two injections of salvarsan, returning within three months with condylomata again, in spite of the fact that mercury was given as well.

After insufficient salvarsan treatment symptoms recur before the mercury which has been subsequently prescribed (usually in the form of pills) has had time to exert its action. Insufficient salvarsan treatment in the early stages of syphilis will do more harm than good, as it gives the patient a false sense of security, and renders him for a longer period a danger to the community. I have seen six cases within the last year of patients who had had two injections of salvarsan infecting others when they themselves thought, and had been told, that they were cured. The cases which recur after several injections of salvarsan and mercury have been given may be roughly divided into two classes: (*a*) those in which the symptoms reappear; (*b*) those in which the Wassermann reaction becomes positive. Oddly enough, the majority of the former gave a negative Wassermann reaction, and the majority of the latter show no symptoms. The interpretation of this paradox is at present not quite clear, but nevertheless the observation is an important one, since the class which cannot be recognised by a laboratory test is dangerous, for the symptoms are usually infectious. Another interesting point is that several of the cases that give a positive Wassermann reaction, but exhibit no symptoms, give a negative Wassermann reaction a few months later, and still show no symptoms.

As to whether salvarsan is more potent than neosalvarsan or *vice versa* different opinions prevail. I have given over 2000 injections of salvarsan, and over 4000 injections of neosalvarsan, controlling both by the Wassermann reaction, and have come to the conclusion that the action of both is very much the same. Neosalvarsan has the advantage of being less toxic and more easily administered than salvarsan, and it is perfectly safe to give it to out-patients.

NOTE ON A NEW COMBINED METHOD OF PROSTATECTOMY

BY J. LYNN THOMAS, C.B., F.R.C.S. ENG.,
SURGEON, KING EDWARD VII. HOSPITAL, CARDIFF.

ABOUT two years ago I was summoned one Sunday afternoon to see a man, in his eighty-third year, suffering from retention of urine. I gave instructions to have him shaved for a possible operation and *not* to pass a catheter. On arrival at the King Edward VII. Hospital I found the patient prepared for another attempt at passing a catheter, which I decided not to do on account of hæmorrhage. His condition was an extremely grave one. His tongue was dry and parched, his breath was strongly urinous in odour, the pupils were very contracted, and he had general subsultus tendinum. The action of the heart could not be felt, and his radial and ulnar arteries were calcified and could be moved from side to side under his wrinkled skin like an articulated stem of a "churchwarden" pipe. Roentgen photographs subsequently taken after recovery showed three long dark tracks in each forearm in the course of the calcified radial, ulnar, and interosseous arteries.

I decided not to tap suprapubically, but to make an incision into the bladder under stovaine spinal analgesia. As soon as the bladder was emptied of fœtid urine I poured about an ounce of pure tincture of iodine into the bladder, before proceeding to enucleate the prostate according to a method which I have adopted for the last seven years, and which was described at the British Medical Association meeting at Sheffield in 1908 and at the Twenty-second Congress of the Association Française de Chirurgie in 1909. I drained perineally after injecting tincture of iodine through the meatus along the urethra into the prostatic bed. Thanks to the assiduous care of my house surgeon, Mr. Owen, in irrigating with hot saline solution for long periods through the suprapubic opening, and to good nursing, the patient made a satisfactory recovery.

There are three points in my operation which require emphasising, as several of my friends who have performed it had not grasped their importance.

1. The first is that the patient is lying on his back as in the ordinary suprapubic operation during the whole of its performance, the perineal opening being made upon the point of the forceps passed transvesically from above, whilst the legs are simply spread apart in order to see and to cut upon the projecting end of the forceps under the skin. The enucleation is as a rule easily done by the forefinger in the bladder, but frequently I pass the other forefinger into the perineal opening to assist the enucleation from below as in the ordinary perineal prostatectomy. The two forefingers enucleating *en rapport* greatly facilitates the performance of those cases which are not easily enucleable.

2. The pouring of pure tincture of iodine into the bladder *before* the enucleation is started is of great importance, because as soon as fresh raw surface is made in the process of enucleation the tincture follows into every hole and corner. The injection of the tincture along the urethra also ensures a cleaner urethra and further floods the freshly made "prostatic bed." Operations can, as a rule, be completed by rubber-gloved hands. (N.B.—There is no danger in using the pure tincture of iodine. I first advocated its use in a paper read at Carmarthen on Dec. 8th, 1904.[1])

3. The operation can be performed as quickly as the suprapubic operation alone. The time I spent in the hospital examining, preparing for operation, completing the operation, and seeing the patient off to the ward was 25 minutes.

Cardiff.

GRESHAM LECTURES, 1914.—Four lectures on the History of Nursing and Florence Nightingale will be given on Tuesday, June 2nd, Wednesday, June 3rd, Thursday, June 4th, and Friday, June 5th, at 6 P.M., by Dr. F. M. Sandwith, Gresham Professor of Physic. The lectures, which are free to the public, will be given at Gresham College, Basinghall-street, London, E.C.

A CASE OF CONGENITAL DEFECT OF THE ULNA.

BY PAUL BERNARD ROTH, F.R.C.S. ENG.,
SURGEON, KENSINGTON GENERAL HOSPITAL; SENIOR ORTHOPÆDIC CLINICAL ASSISTANT, LONDON HOSPITAL.

Congenital defect of the ulna is an extremely rare condition. When Wierzejewski recorded a case in 1910 he was only able to collect 22 others from the literature. His paper[1] is the most complete account of this condition yet published, and is furnished with a comprehensive bibliography. He accepts the classification of Kümmel,[2] who divides the cases into three groups, as follows:—

A. The ulna is partly or completely absent; the radius is normal, though often curved; the ulnar fingers are absent.

B. The ulna is partly or completely absent; the radius is ankylosed with the humerus at a more or less obtuse angle; when a proximal part of the ulna is present it also is fused with the radius and humerus.

C. The ulna is partly or completely absent; the upper end of the radius is dislocated forwards and upwards on the humerus.

It is to Group C that the present case belongs. Of the 23 cases, including his own, Wierzejewski placed 7 in Group A, 6 in Group B, 7 in Group C, and 3 he classed as doubtful. As regards sex, 13 occurred in males, 7 in females, and in 3 the sex was not stated. In 7 cases the defect was bilateral; in 4 of these both ulnæ were completely missing, and in 1 case the defect was total on one side and partial on the other. Of the 16 cases where the defect was unilateral, in 11 it was on the right side and in 5 on the left. In 12 cases the defect was total. In 11 where it was partial, in 8 the distal end failed and in 3 the shaft.

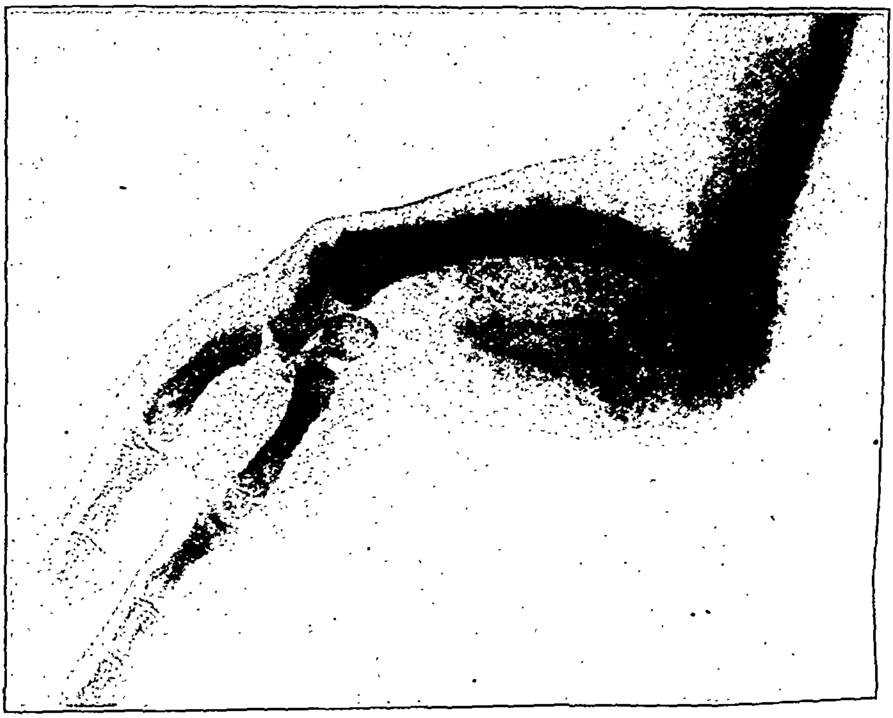
The patient in the case here recorded, a girl aged 7, attended hospital on March 31st. Her aunt stated that the child's left arm had been withered since birth, and that lately it was becoming more crooked. She is the second of three children; her own birth was normal, but her mother died in giving birth to the third child, who died also. There is nothing abnormal in the family history. On examination the following condition was found. The left upper extremity is defective; the lower two-thirds of the ulna together with three digits are absent; the upper end of the radius is dislocated forwards and upwards on the humerus, and the shaft of the radius is markedly curved, with convexity outwards. Of the two digits present one is undoubtedly the thumb, while the other has all the appearance of the little finger. The hand, the palm of which seems to consist solely of a thenar and hypothenar eminence, is deflected to the ulnar side, so that its ulnar margin forms almost a right angle with the ulnar side of the forearm. Except that it is 1 inch shorter than its fellow of the opposite side the left humerus appears normal. (Tip of left acromion to external condyle of left humerus = 7¼ inches; tip of right acromion to external condyle of right humerus = 8¼ inches.) With regard to voluntary movements, the elbow can be flexed and extended completely with good power; the hand can be completely supinated, but from the fully supinated position can only be pronated through 90°, inability to pronate it further being apparently due to the curvature of the radius. The wrist can be flexed or extended completely; the thumb and finger can also be fully flexed or extended, and also abducted and adducted, but the thumb cannot be opposed to the finger. These two digits are of great use to the child, being used to hold material when sewing, and for doing up her clothes, &c.

---

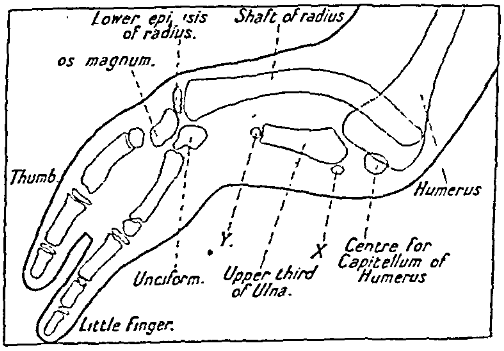
[1] Wierzejewski: Zeitschrift für Orthopädische Chirurgie, Band xxvii., 1910, pp. [illegible].

[2] Kümmel, quoted by Wierzejewski, Die Missbildung der Extremitäten durch Defekt, Verwachsung und Ueberzahl. Bibliotheca medica Abt. E, H. 3, Cassel, [illegible].

The radiogram taken the next day by Dr. W. Ironside Bruce shows many interesting features. The humerus is apparently normal, and the ossific centre for the capitellum is well marked. Of the ulna, only the upper third is present. Immediately beneath the proximal extremity of this is a small ossific centre X (see radiogram and explanatory diagram); this may be the centre for the tip of the olecranon process, which does not, as a rule, appear so early, or it may be, as Dr. Bruce suggests, the centre for the head of the radius, from which the shaft has been completely separated. One-third of the way down, the shaft of the ulna terminates abruptly in a stump, the lower end of which is slightly cup-shaped. Directly distal to this lower end is another small ossific centre Y (see illustration and key), the size of a peppercorn; this is either the lower epiphysis of the ulna, or more likely, the cuneiform bone. The radius is so much curved that it forms the fifth part of the circumference of a circle, the convexity of the curve being directed upwards and outwards. The upper end does not articulate with the ulna and capitellum, but is dislocated forwards and upwards, lying on the anterior aspect of the lower end of the humerus, apparently articulating in the "radial depression." The centre for its upper epiphysis is absent, unless indeed it is represented by the centre X already described. The lower end of the radius is slightly malformed, but the centre for its epiphysis is present and well marked. At the wrist the centres for two carpal bones are present, and there is also the previously mentioned centre for the cuneiform. An inspection of radiograms of the wrists of normal children of this age only reveals the presence of three carpal bones—the os magum, unciform, and cuneiform, and it is therefore reasonable to suppose that the three centres present in this case are for these bones. Later on centres for other carpal bones may appear. Two complete digits are present: one is a thumb, and the base of its metacarpal is opposite the os magnum; the other has no special distinctive features—the base of its metacarpal is opposite the unciform. There is no sign of the other three digits.



Radiogram showing congenital defect of ulna.



Key to radiogram.

Treatment.—Since birth no attempt has been made to keep the hand in line with the forearm, and the patient has now only come under observation because of the increasing deflection of the hand to the ulnar side. The hand and wrist are now being regularly manipulated every day, and it is hoped that in a few months part of the ulnar deflection will be got rid of. In addition to this a celluloid splint will be worn at night to retain the upper arm, forearm, and hand in as straight a line as possible. If these measures do not meet with the hoped-for success, the advisability of the removal of a wedge of bone from the shaft of the radius will be considered.

Harley-street, W.

GLASGOW UNIVERSITY CLUB, LONDON.—The summer dinner of this club will be held at the Trocadero Restaurant, Piccadilly Circus, W., on Wednesday, May 27th, at 7.15 for 7.30 o'clock, under the chairmanship of Emeritus Professor John Cleland, M.D., F.R.S.

SECONDARY OR SYMPTOMATIC LEUKÆMIA.*

BY GORDON R. WARD, M.D. LOND.

THE division of anæmias into primary and secondary has long been practised and accepted. That a similar division of leukæmias may conveniently be made it is the object of this paper to demonstrate.

What is ordinarily called leukæmia the writer would call primary leukæmia, and this may be regarded as a disease of which the chief clinical and pathological features reflect the response of the blood-forming organs to a stimulus of which the nature is unknown. It is convenient to suppose that this stimulus is produced by the excessive destruction of white cells within the body, just as after a sublethal but toxic dose of benzene the red cells are destroyed in the body and their products give rise to a very extensive and irregular reaction of those blood-forming organs which are concerned in the formation of red cells.

In leukæmia, then, and in response, as we more or less plausibly suppose, to excessive leucocyte destruction, the blood-forming organs show a great and irregular exaggeration of white-cell formation. Nor is this confined to the marrow, glands, and spleen—i.e., the normal blood-forming organs of the adult. The liver also takes a share, and after death we find in Glisson's capule a by no means inconsiderable amount of tissue which is morphologically (and presumably functionally) identical with that of the marrow or glands as the case may be. In this condition of the liver we have one of the surest criteria of the presence of leukæmia. Further search will reveal similar growths in other organs and in organs which are not associated with blood formation even in fœtal life. But in all these situations we must assume the presence of primitve cells which are capable of forming blood cells under the influence of a sufficiently powerful stimulus.

Now in primary leukæmia we have the most powerful of all stimuli—viz., an excess of the products of leucocyte destruction—and consequently the resulting changes are better marked than in any other condition. Almost invariably, for example, there is so great a proliferation of white cells that the blood shows two or three hundred times the normal number of white cells. This, however, is not an essential of the disease; we know little or nothing of the mechanism by which the cells of the marrow are shed into the blood stream, but clinical observation sufficiently attests that this is a very variable factor even in the individual case of leukæmia, and that the blood may in some cases or at some times be practically normal. Hence, although a "leukæmic blood picture" is good evidence of the changes in the organs detailed above, its absence by no means excludes such changes.

It may be at once stated that in secondary leukæmia the full picture of primary leukæmia is rarely met with, just as in the secondary hæmolytic anæmias—e.g., chronic benzene poisoning—the full, so-called "pernicious," blood picture of Addisonian anæmia is not often met with. Histologically the secondary leukæmias fall naturally into two classes—viz., secondary lymphæmia and secondary myelæmia, these being the usual divisions also of primary leukæmia. The former seems to be especially associated with septic diseases, the latter with cancer.

Clinically, and here it must be admitted that much more information is necessary before anyone can venture to speak with assurance, it seems that we can recognise certain classes of cases more often associated with secondary leukæmia than others. Of course, in all these cases the leukæmia is purely a symptom; it is secondary to obvious or plausibly conjectured causes. Some of these classes can now be discussed.

Secondary leukæmia in septic processes.—Cabot[1] has put on record 4 cases in which there was a blood picture so similar to that of primary lymphæmia as to cause considerable misgiving to the attending physicians. Yet all these cases made a good recovery, and one at least was known to be well 15 years later. In the latter case the lymphocytes reached 70 per cent. of all white cells. It was that of a young physician who infected his finger at a necropsy, and had thereafter swelling of the glands in the axilla of the same side and later in the opposite axilla also. In the next case, one of persistent boils, the lymphocytes reached 86 per cent., and it is further noted that they were unlike the ordinary hæmic lymphocyte in that they showed mitotic figures and other irregularities. One may legitimately attach some importance to this fact when a diagnosis of leukæmia as against lymphocytosis is under consideration. Cabot's other two cases were of a more doubtful type. The blood, indeed, was that of leukæmia, but the clinical signs seem to have been very indefinite. In both sore-throat and enlargement of the glands were present. Dr. J. A. Braxton Hicks, of the Westminster Hospital, informs me that he has seen a similar case, and I remember also a case under the care of Dr. A. M. Gossage in the same institution which presented a lymphatic blood picture and swelling of the glands with a septic condition of the mouth. These cases all made a good recovery and no necropsy was possible.

Lindsay Steven[2] reported a case of broncho-pneumonia in a child aged 1 year and 10 months, in which the white cells reached 236,000 per c.mm., of which 65 per cent. were mononuclears. They are referred to as lymphocytes, but Dr. W. K. Hunter, who examined some of the films, notes that several stained abnormally, so we may assume that they were allied to the abnormal lymphocytes which one expects to meet with in leukæmia. The patient died, but the account of the necropsy is devoted to the condition of the lungs. Cabot[3] also reports two cases of pneumonia in children aged 1 year and 3 months, and 6 years. Both seem also to have had pertussis. In the first the white cells reached 185,000 with 64 per cent. of lymphocytes, and the second 94,000 with 66 per cent. of lymphocytes.

Austrian[4] reports a case of broncho-pneumonia with mastoiditis in a child, aged 4, which proved fatal. The white cells reached 192,000, and the percentage of myelocytes was from 10 to 14. This is not a high percentage, but a little arithmetic shows that the total number of myelocytes per c.mm. was over 23,000. There was also a varying percentage of cells which could not be classified under any of the ordinary headings, and these were, perhaps, myeloblasts. The necropsy showed "marked hyperplasia" of the marrow, although there were "still some areas of fat remaining."

---

* An abstract of a paper read before the Medical Section of the Royal Society of Medicine, [illegible]

The "large neutrophil myelocyte" was the predominant cell. The Malpighian bodies in the spleen were grey and "tremendously enlarged." The parenchyma of the liver was infiltrated with mononuclear cells and occasional myelocytes. The bronchial and mediastinal glands were much enlarged. On these facts the presence of a process to which the name "leukæmia" may properly be given seems established. This is the most complete case that I am able to bring forward in this class.

Morawitz[5] records a case in which the patient was aged 16 and suffered from "a feverish malady of the heart without sequelæ." The white cell count was always low, but the myelocytes reached 15 per cent., and of these 1·5 per cent. were eosinophil myelocytes. Recovery was complete. Hirschfeld and Kothe[6] report a case of gangrenous appendicitis complicated by hæmorrhage from a duodenal ulcer in a boy aged 10. The white cells reached 190,000 and the myelocytes 7 per cent.

Fractures and secondary leukæmia.—The second class of cases to which one draws attention with some diffidence comprises those in which a fracture has been accompanied by peculiar blood changes. The classical case is that of Simon,[7] in which an adult negro sustained a fracture of the ankle by having the leg crushed. On admission to hospital the blood showed merely a polymorph leucocytosis, but a week after the following changes were noted —viz., the wound was septic, the spleen was enlarged, and the blood showed 50,000 white cells with 15 per cent. of neutrophil myelocytes, 1·2 per cent. of eosinophil myelocytes, and 17·5 per cent. of mast cell leucocytes. A week later the blood was almost normal, and three months later was still normal. Simon appears to have been at some pains to search the literature for similar findings, but with little result. He says, however: "Hastings writes me that in two cases he has seen myelæmia with myelocytes between 3 and 7 per cent., the one being a severe crush of the thigh and femur, and the other one of the forearm, with no break in the skin and no evidence of infection."

Wiczkowski[8] records the case of a man, aged 24, who also sustained a crush of the ankle, and in whom the inguinal glands on the side of the crush were enlarged ten days later. Soon all the glands and the spleen were enlarged, and the white cells reached 590,000 per c.mm. The patient died, but no necropsy was permitted. It is a peculiar coincidence that Hirschfeld and Kothe[6] also report a case, aged 16, in which there was a fracture of the leg and a leucocytosis of 108,000, but no differential count is given.

Sepsis was probably a factor of importance in most of these cases, and there is not sufficient evidence to incriminate the fractures *per se*.

Cancer and secondary leukæmia.—The first case has not yet been published. It is that of a woman, aged 47, who was under the care of Dr. R. Hutchison at the London Hospital. She was also seen by Dr. F. Parkes Weber. The pathological report will be published by Dr. H. M. Turnbull shortly. I am extremely indebted to these gentlemen for the kindness with which they have permitted me access to the records of the case, and especially to Dr. Turnbull, who has shown me all the sections and specimens connected with it.

The patient died from cancer of the breast and during life was very anæmic. The white cells were 22,000 per c.mm. and the myelocytes 8·5 per cent. It is of interest that a blood count of this sort, which might be paralleled from the records of all sorts of widely differing diseases, was nevertheless associated with extremely extensive myeloid changes in all the organs. At the necropsy the marrow was found to be almost entirely replaced by cancerous infiltration, and the same was true of the spleen, the liver, many of the glands, and the affected breast. The other breast was free from cancer, but nevertheless showed considerable areas of tissue which was composed of cells such as are met with in the marrow. Such tissue was also found about the cancer growths in other organs. It contained not only neutrophil and eosinophil myelocytes, but also foci of red-cell formation in the centre of which were seen primitive nucleated red cells and at the periphery those more fully formed. The red cells in the blood also showed the changes which one meets with in primary myelæmia. Nevertheless there were still some fatty areas in the marrow itself.

The case of Kurpjuweit[9] was very similar. The patient was a woman aged 34. The primary disease was in the stomach. The liver, spleen, and some of the glands showed myeloid transformation. The blood showed 11 per cent. of myelocytes, but the total number of white cells was not increased.

In the case of Kast,[10] a man with carcinoma of the penis of 18 months' duration, the spleen was myeloid and contained Charcot-Leyden crystals; the marrow contained the same crystals. The glands that did not contain cancer were myeloid. The white cell count was rather remarkable, the numbers reaching 120,000 per c.mm., but the myelocytes were only 1 per cent.

Other cases of secondary leukæmia.—Emile Weil[11] investigated cases of variola before suppuration had set in, and found remarkable changes in the blood which were of short duration, being displaced by a polynuclear leucocytosis later. He remarks apropos of the blood picture: "En meme temps coexiste toute la série des formes leucocytaires qu'on peut voir dans la leucémie myélogène." He also finds nucleated red cells but rarely except in the hæmorrhagic form. He claims that he is the first to describe this "syndrome." Courmont and Montagard[12] covered the same ground, and agreed with his "leukæmic" finding.

Labbé and Delille[13] record a case of hereditary syphilis in a child 1 month old with enlarged spleen. The white cell count was increased, and the mononuclears were altogether 85 per cent. Of these 50 per cent. were large mononuclears. In the discussion which followed his communication, several speakers emphasised the fact that this "anémie pseudo-leucémique" was only a symptom and not a disease, and might be met with in syphilis, rickets, tuberculosis, and intestinal infections. Dominici[14] carried out some experiments on dogs with the idea of producing myeloid changes, and seems to have been very successful in experimental tuberculosis, typhoid, sepsis, and potash poisoning. He remarks that the hæmopoietic organs react as a whole to these poisons, but do not bring the changes into comparison with those of primary leukæmia.

Dr. Turnbull informs me that he has always taught that the splenic anæmia of infancy described by von Jaksch was a myeloid leukæmia, and very kindly showed me slides from several cases which certainly seem very strongly to support that contention.

Conclusion.—It is submitted that the above cases considered alone are sufficient justification for a division of leukæmia into primary and secondary.

It is quite true that primary leukæmia, of which the cause is not established, may be due to some micro-organism which will eventually be identified. Then all leukæmias will take their proper places as symptoms of the specific infections or other disease processes with which they are associated. The so-called primary anæmias are already reaching the stage to which leukæmias must eventually come. No progress, however, is likely to be made with the study of leukæmia clinically until subdivisions are established, and in this case the idiopathic varieties are properly and according to precedent labelled primary until their true nature can be established.

BACILLUS COLI AS A CAUSE OF SEPTIC ONYCHIA.

BY THOMAS HOUSTON, B.A., M.D. R.U.I.,
PHYSICIAN-IN CHARGE OF THE DEPARTMENT OF HÆMATOLOGY AND VACCINE THERAPY, ROYAL VICTORIA HOSPITAL, BELFAST;
AND
W. W. D. THOMSON, B.A., M.B., B.Sc. BELF., D.P.H.,
RIDDELL DEMONSTRATOR OF PATHOLOGY, QUEEN'S UNIVERSITY, BELFAST, AND CLINICAL PATHOLOGIST, MATER INFIRMORUM HOSPITAL, BELFAST.

THREE cases have recently come under our notice of septic onychia due to infection by the bacillus coli.

One of these cases occurred in a medical man who was attending a case of bacillus coli cystitis, which he was treating by lavage of the bladder. He developed a very painful swelling, red, tender, and œdematous, round the roots of two nails. In both the affected fingers there was a history of a minute abrasion. These were treated by incision and cauterisation without effect. Two doses of stock staphylococcus vaccine produced no improvement. A culture taken from the sero-purulent discharge which exuded from beneath the swelling contained as well as some staphylococci and diphtheroids, bacilli coli, morphologically and culturally typical. The patient's opsonic index to the bacillus coli was found on two occasions to be raised above 2. His serum did not agglutinate the bacillus coli. A vaccine of this micro-organism was administered, and after the first dose of 2½ millions immediate improvement set in, and it was only necessary to administer a second dose to secure a complete cure. Both nails were lost.

The second case was that of a lady with a curious condition of the nails. The lesions resembled psoriasis and had been diagnosed and treated unsuccessfully as psoriasis. The condition had first appeared 15 years ago and had lasted for one year and then disappeared. Four years ago it returned and had persisted ever since. The margin of skin around the nails at intervals became swollen and discharged pus. This patient was troubled with constipation, "bilious turns," and headaches. The pus from the fingers contained bacillus coli in pure culture. She was treated with a bacillus coli vaccine (autogenous). Vaccination was followed by marked benefit. Her fingers on the last occasion on which she was seen were practically well. Her general health was also greatly improved. The reaction from the vaccine caused the fingers to inflame and was accompanied by diarrhœa and sickness.

The third case was one of very severe onychia. A swab taken from this case yielded on culture bacilli coli and staphylococci. Here again vaccine treatment with the patient's own strain of bacillus coli was of value. In these two latter cases no obvious source of infection was discovered.

We thought that these cases were of sufficient interest and importance to report, as we have been unable to discover any previous record of onychia due to this organism.

A CASE OF TETANUS TREATED WITH SUBCUTANEOUS INJECTIONS OF CARBOLIC ACID; RECOVERY.

BY W. GRAHAM REYNOLDS, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON, HOUSE PHYSICIAN, AND RESIDENT OBSTETRIC OFFICER, ST. MARY'S HOSPITAL, LONDON.

THE patient, a boy aged 11, was paddling in a canal when he cut his foot on a piece of glass. Ten days later he complained of stiffness in his neck. For the next four days there was increasing difficulty in moving the head, and the muscles of the lower jaw showed signs of rigidity. On the fourteenth day from the date of the accident the spasms started, and he was admitted to St. Mary's Hospital during the evening.

On admission general rigidity was seen, and there was well-marked opisthotonos. Abdominal spasm was particularly evident, and there was inability to open the mouth. The risus sardonicus was also present. He had very frequent and severe spasms, but was mentally quite clear. There was a very small wound, nearly healed, on the dorsum of the right foot, one inch from the cleft between the second and third toes; there was also the scar of a small recent cut in the cleft between these toes.

The patient was anæsthetised. The wound and the scar were excised and pure carbolic acid was applied. At the same time the subcutaneous injection of carbolic acid was started, 1 oz. of a 1 per cent. solution being given in the right axilla. Under chloroform anæsthesia the injections were repeated as in the list, the strength of the carbolic solution being raised to 3 per cent. The groins and axilla were treated alternately. Chloroform was administered at each injection owing to the spasms produced by the stimulation of the needle-prick. A careful watch was kept for carbolic acid poisoning, but at no time did the patient show any symptoms. The urine retained its normal colour throughout.

On the day following admission the spasms became very violent, and the child suffered great pain. Potassium bromide gr. xx. and chloral hydrate gr. x. were administered four-hourly, and the patient became quieter. On the sixth day cutaneous erythema and slight œdema were noticed at the sites of injections, and these were discontinued. The spasms were increasing in violence and frequency, and the carbolic solution was again administered on the seventh day.

The injections were discontinued on the eighth and ninth days, but were recommenced at 2 A.M. on the tenth. On the thirteenth day the opisthotonos became very marked, and it increased during the following six days. By the twentieth day it had become excessive, although the spasms decreased both in violence and in frequency. On the same day the opisthotonos suddenly began to diminish, and had entirely disappeared by the twenty-third day.

The rigidity, especially that of the abdomen, did not relax for some time; in fact, this did not disappear for about seven weeks. The patient was able to open the mouth slightly about the sixteenth day, and by the eighteenth was eating bread and butter. Improvement continued uneventfully during the next four weeks, and he was discharged cured on the fifty-sixth day. He was seen three weeks later on return from a convalescent home, and was in perfect health. No antitetanic serum was administered.

The chief interest in this case lies in the fact that the carbolic treatment, recommended so long ago as 1888 by Bacelli, but which has never gained many adherents in this country, was adopted throughout, and also the fact that at the time, when for the reasons stated it had to be discontinued, the spasms increased in number and violence, the recommencement of the injections at once modifying these attacks. This does seem to prove that carbolic acid has a definite action in inhibiting the reflex activity in the cord.

It would be interesting to hear the results of others who have tried this treatment, and to know the dosage they employed.

I have to thank Mr. J. Ernest Lane, senior surgeon to St. Mary's Hospital, for permission to publish this case.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RODENT ULCER IN AN UNUSUAL SITUATION.

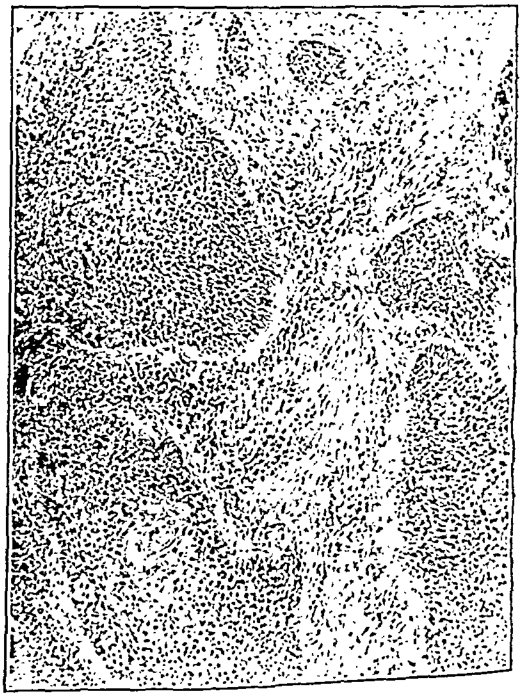
By MILNE MCINTYRE, M.B., CH.B. GLASG.,
DISPENSARY SURGEON, GLASGOW ROYAL INFIRMARY.

RODENT ulcer is a common affection when found on the face, particularly on the upper third, and mostly about the inner canthus of either eye. On any other part of the body it is decidedly rare, and for this reason its occurrence elsewhere than on the face is worthy of note.

The patient, a woman 52 years of age, was admitted to the Glasgow Royal Infirmary during November of last year for treatment of a large slowly spreading ulcer situated on the back between the scapulæ and towards the right side. It commenced nine years ago as a small wart, which for some time was unheeded, till it ulcerated and discharged, when she sought advice. Since then it has gradually increased in size, though under treatment apparently healing over from time to time, and as often breaking down again; but for the last two years the discharge has been constant, with progressive increase in size.

On admission an ulcer about the size of the palm of an adult hand occupied the above situation, extending down to the fascia covering the muscles of the back. There was no tumour, the condition being purely spreading ulceration. The base was fixed, the outline irregular, and the floor pale, free from granulations and exuding a scanty, sticky, muddy discharge. The edges were slightly raised, indurated, and sinuous in outline. Parts of the surrounding skin had a dusky hue from passive congestion, and, though full from œdema, extended otherwise unaffected right up to the margin of the ulcer. The patient's general health suffered little in consequence, and there was no evident glandular involvement or metastasis elsewhere. The ulcer was completely excised and the raw surface treated with carbon dioxide snow.

Histological examination.—The sections prepared were from the margin of the ulcer, and present the characters of a rodent ulcer. Broad processes of the deeper layers of the epithelium are observed dipping deep into the corium. The cells are arranged in groups varying in size, discretely scattered through a fibrosed corium. They are all alike in type, resembling the cells of the deeper layers of the epithelium, but differing among themselves a little in size and shape, many showing mitotic figures. A few of the cell groups have a necrosed centre, the stratum corneum is atrophied, and there are no cell nests.



From a microphotograph.

Glasgow.

AN UNUSUAL PERI-SINOUS ABSCESS.

By HAROLD L. WHALE, M.D. CANTAB., F.R.C.S. ENG.,
SURGEON FOR DISEASES OF THE EAR, THROAT, AND NOSE, LONDON TEMPERANCE HOSPITAL AND HAMPSTEAD GENERAL HOSPITAL.

A GIRL, aged 5, was seized with earache and vomiting on Christmas Day, 1913. On admission to hospital on Dec. 29th she presented the stereotyped signs and symptoms of acute suppurative mastoiditis. Except measles two years previously, and mild recurrent earache for one year, inquiry elicited no relevant history. The membrane was bulging but intact; the retro-auricular swelling was tense and fluctuating.

A Schwartze operation was at once instituted. The periosteum was found to be lifted up by a bag of pus, but deep to this the outer antral wall was intact and healthy. Beginning at a point one-eighth of an inch behind the surface marking of the posterior limit of the antrum and running backwards for nearly an inch was a fistula one-eighth of an inch wide, quite straight and quite horizontal; nearly an ounce of thick foul pus gushed through this slit. On removing the outer antral wall it was evident that the pus in the antrum, a mere bead, had no macroscopic connexion with that which lay along the horizontal part of the lateral sinus; the finest seeker detected no fistula. In front, the purulent focus was shut off by adherent dura, so as to end abruptly at the upper genu of the sinus, where its horizontal passes into its sigmoid limb. The edges of the bony fistula were widened with a chisel to a quarter of an inch, and with simple drainage recovery was uneventful.

This case presents certain points of interest. 1. It is not without precedent for an acute otitis media to lead to acute mastoiditis without perforating the membrana tympani; nor, again, for an acute antritis to proceed to intracranial infection without finding its way through the outer antral wall. But the double event, which happened in this case, is very rare—that is, for an acute otitis media not only to leave the drum intact, but also to show no evidence of assault on the antral wall, and first to declare itself remotely as pus in the posterior fossa. 2. If, in explanation of the route selected in this case, we invoke the line of least resistance, the possibilities are: first, the saccus endolymphaticus by the aquæductus vestibuli (but during this journey the infection must have caused labyrinthitis, whereas this patient had no nystagmus, vertigo, or interference with vestibular reactions); or, secondly, one of the sutures, after delayed or imperfect closure between the component parts of the temporal bone. In this latter event, if the infection had travelled by the petro-mastoid suture, it would have reached the middle rather than the posterior fossa, and there would have been no visible external fistula; if by the squamo-mastoid suture, the dehiscence would have been directed obliquely upwards and backwards. There is no anatomical reason for a fistula extending horizontally backwards, and the route taken is therefore not easy to explain. 3. It is very uncommon for a peri-sinous abscess to track along the horizontal part without also, and as a rule previously, involving the vertical part of the lateral sinus.

Harley-street, W.

ROYAL WEST SUSSEX HOSPITAL.—There has been no more eventful year than 1913 in the history of this hospital at Chichester—one of the best-equipped and best-served hospitals in the south of England. After extensive reconstruction work the institution was visited by King George, who declared it re-opened as a Royal hospital in memory of his illustrious father. The whole cost of that reconstruction scheme was met, and on that account there is a small balance in hand. The income account showed a deficiency of £210 7*s.* 6*d.*, and in spite of the strictest economy it is found that the ends are not meeting. An annual income of £4200 is necessary if the hospital is to be kept going as now, and an earnest appeal is being made for at least another £500 a year in addition to the existing income. Although a broken year, owing to the extensive reconstruction work, the in-patients numbered 510 and the out-patients 2640.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

The Relation of Ducts and Acini to Cysts and Cancer of the Breast.

A MEETING of this section was held on May 12th, Mr. G. H. MAKINS, the President, being in the chair.

Mr. G. LENTHAL CHEATLE read a paper on the Relation of Ducts and Acini to Cysts and Cancer of the Breast. He said that in proof of the ducts being the cause of cysts he would state that: (*a*) In the normal state the columnar type of cell which lined the ducts extended to the acini, but was not continued into them. Cysts were lined by the same epithelium. (*b*) An accidental injection by a central hæmorrhage occurred in a cystic breast. The only parts injected with blood were the normal ducts, and even the acini, and also the cysts. (*c*) The cysts could be shown opening into acini. The acini were not dilated. Single cysts, although apparent clinically as such, were always coexistent with smaller cysts, which were easily made manifest by microscopical examination. It was hard to understand why cysts formed. He believed they formed to accommodate the proliferating epithelium. Obstruction to ducts might conceivably induce cystic formation, but it would not be likely to cause the intracystic papillomatous condition which was so common in cysts. The hæmorrhagic breast to which he had alluded appeared to confirm the idea that no obstruction existed, because all the ducts, acini, and cysts were full of blood. Acini would be more likely to be dilated were obstruction the cause of the cystic condition of ducts. Duct cancer divided quite obviously and naturally into two types—(*a*) intracystic papillomatous, and (*b*) intracystic "laciform." 1. Each, even when type appeared present, was more or less mixed. 2. Each in its spread showed alveolar arrangement in parts. Hence to discover the origin of an alveolar cancer of the breast large sections, and possibly extensive serial sections, might have to be made. It must be noted that even in the alveolar arrangement there was a tendency for each to become typical of its origin. 3. Each showed simple cystic conditions. 4. The lymphatic glands, when affected, showed the intracystic "laciform" type. He had not yet discovered the intracystic papillomatous type in a lymphatic gland. With regard to the relation between acini and cysts, he had no evidence to prove or even indicate that one existed, nor that there was any relation between acini and cancer. In his 250 cases of cancer of the breast 45 per cent. were duct cancer in origin. Of the remaining 55 per cent., some might have been of similar origin. In no case could he trace a definite connexion between cancer and acini. He did not mean to say it did not exist. Probably at wanted only definite proof. An alveolar arrangement certainly was no proof.

Mr. Cheatle then gave an exhibition by the epidiascope of 52 macroscopic and microscopic preparations of duct cancer of the breast in support of his contentions.

SECTION OF LARYNGOLOGY.

Exhibition of Cases.

A MEETING of this section was held on May 1st, Dr. D. R. PATERSON, the President, being in the chair.

Dr. W. MILLIGAN showed X ray bismuth photographs of three patients with Pharyngeal Pouches. An external operation was performed in the three cases; one died from septic pneumonia (probably due to food ingestion).—Dr. G. W. HILL advised Halstead's operation, in which the unopened sac was dissected out and turned upwards into the upper angle of the external wound. At a second operation after the formation of adhesions the sac was removed. He considered the photographic method better than œsophagoscopy for diagnostic purposes.

Dr. MILLIGAN also brought exhibits of Inoperable Thyroid Gland and Fungating Œsophageal Carcinomata treated by radium emanation tube He pointed that out it was essential to exclude the α and β rays and utilise the γ rays by suitable filters. Irradiation of healthy tissues was dangerous.—Sir **FELIX SEMON** related an instance where radium caused sloughing with fatal mediastinitis.—Mr. W. D. **HARMER** had found that external insertions of 150 mgm. of radium for 18 hours resulted in a wound which did not heal.—Dr. **HILL** laid great stress on the filtration. He had employed 150 mgm. with a screen of 2 mm. of platinum covered with rubber for 18 hours without injurious effect.—Mr. S. **HASTINGS** in 18 cases had found sloughing in one case where septic teeth were present. He placed the radium in a Symonds' funnel and inserted it by means of an œsophagoscope.

Mr. E. A. **PETERS** brought forward a case previously exhibited with left unilateral abductor paralysis, but which now had progressed to complete paralysis with the cord in a cadaveric position.

Dr. J. **DONELAN'S** two cases of Papilloma of the Vocal Cords, in which he had found it easier to employ the indirect instead of the direct method, were discussed by Sir **STCLAIR THOMSON**, who related that both Killian and von Eicken preferred the indirect method where this could be employed. Indeed, by the old principle of *cito, tuto et jucunde* the indirect method came first.—Sir **FELIX SEMON** remarked that the need for good technique in the application of the indirect method had constituted laryngological work as a specialty, accordingly he regretted the disuse of this method by the younger men.—Dr. **HILL** pleaded for the simplicity of direct laryngoscopy, and mentioned the tolerance of chronic tuberculous patients to its use. He also considered that suspension laryngoscopy would still further diminish the field of the indirect method.—Mr. E. B. **WAGGETT** upheld indirect laryngoscopy.—The **PRESIDENT** considered that where a general anæsthetic had to be employed the direct method was preferable, in other cases the indirect. The advance from the days of Hartmann's direct spatula to the present duck-billed tubes was remarkable.

Dr. W. **JOBSON HORNE** showed a case of Laryngeal Neoplasm which Mr. H. C. **FOX** and Mr. J. F. **O'MALLEY** considered to be attached to the anterior commissure; also an extreme case of Congenital Webbing of the Palate.

Dr. L. H. **PEGLER** brought a case with an Œdematous Fibroma depending from the left vocal cord.

Mr. C. I. **GRAHAM** exhibited a case of Chondro-Sarcoma of the Pharynx.

Mr. P. R. W. **DE SANTI'S** case of Lupus of the Nose, Ear, and Tongue and Pharynx was discussed. The Wassermann reaction was only partially positive on one occasion; giant cells, but no tubercle bacilli, were recognised in a microscopical preparation.

Mr. C. **POTTER'S** case of Perithelioma of the Pharynx, which was enucleated with the capsule by an incision through the mucous membrane, was referred to Mr. S. G. Shattock.

In Dr. **HILL'S** case of Carcinoma of the Base of the Tongue and Epiglottis Mr. **DE SANTI** recommended a subhyoid pharyngotomy through a central incision.

SECTION OF OTOLOGY.

Primary Tuberculosis of the Ear.—Exhibition of Cases.

A MEETING of this section was held on May 15th, Mr. **RICHARD LAKE** being in the chair.

Dr. W. **JOBSON HORNE** described a case of Primary Tuberculosis of the Ear in a child aged 13, in which the diagnosis was established by the finding of tubercle bacilli in the tissues over the necrosed portion of the temporal bone, which he exhibited. There had been a cough for three months, and the child had been wasting seven months; there had been measles two months ago. Fifteen days before death facial paralysis developed, and the child died with signs of cerebral disease. There had been a discharge from the right ear for about four months. Post mortem the temporal bone and membrana tympani were found to have been destroyed, the ossicles had perished, and the middle ear was disorganised. The antrum and middle ear were filled with débris and caseous matter, and the cancellous portion of the mastoid was involved. Above and behind the external auditory meatus a subperiosteal abscess was found, and at its site a sharply defined area of necrosed bone corresponding to the outer wall of the antrum. On deflecting the dura mater from the cranial surface of the bone an extradural abscess was found and some tuberculous deposits. There were also found extensive disease of the lymphatic glands, general miliary tuberculosis, tuberculous meningitis, and tuberculous nodules in the brain. Dr. Horne expressed the opinion that primary tuberculosis of the ear presented such definite clinical and pathological features that it could easily be distinguished from the secondary form of the disease. Primary tuberculosis of the ear was essentially a disease of childhood, if not even of infant life. This case also illustrated the exhibitor's contention that in the primary form the stress of the disease was, in the first instance, on the mastoid bone.—Mr. C. E. **WEST**, in discussing the case, said that bone tubercle was very rarely primary in the sense of being the site for the first deposition of tubercle in the body; it was nearly always preceded by a focus, generally a caseating one, in the lymphatic glands. Supposed tubercle of the temporal bone in children he believed to be much rarer than was generally supposed. The operative results on these cases, though good at the time, were unfavourable later, for 50 per cent. died from tuberculous meningitis three or four years afterwards.

Dr. E. A. **PETERS** and Dr. H. J. **DAVIS** showed interesting cases of Exostoses of the External Meatus, and the advisability of operation in such instances was discussed. Dr. Davis also showed a remarkable case of Recovery from Operations, at different dates, on two large temporo-sphenoidal abscesses. The patient, a girl aged 16, was shown a year ago after recovery from an abscess on the right side, and three months ago she again presented herself with similar symptoms on the left side—namely, earache, vomiting, and vertigo—and an aural polypus was protruding from the meatus. Owing to great restlessness, aphasia, and rapid unconsciousness, with rotatory nystagmus to the right, and signs of meningitis, he, with the assistance of Mr. Addison, opened and drained a large temporo-sphenoidal abscess. The brain was motionless and on incision pus and a quantity of sanious fluid streamed from the lobe, which then commenced to pulsate. Salines were continuously administered, and Mr. Addison performed lumbar puncture. As the pathologist reported that pus was found in the cerebro-spinal fluid the prognosis was regarded as hopeless. Dr. J. M. Bernstein and Dr. Elworthy, who also saw the case, recommended intraspinal injections of antistreptococcus serum, and 10 c.c. were given twice at 24-hour intervals. She also had three vaccine injections in the flank, and was kept alive on champagne, pituitrin extract, &c., and her recovery, though slow, was uneventful. She was now bright and the aphasia had disappeared, but she could only hear the tuning fork on contact.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Empyema in Children.—The Pathology and Etiology of Duodenal Ulcer.

A MEETING of this society was held on May 6th, Dr. **JOHN PLAYFAIR**, the President, being in the chair.

Dr. **NORMAN WALKER** showed a case of advanced Mycosis Fungoides apparently cured by the application of X rays, only pigmented areas remaining.

Dr. G. H. **MELVILLE DUNLOP** contributed a paper on Empyema in Children, based upon 98 cases treated in his ward in the Sick Children's Hospital. He pointed out that during the same period in which these empyema cases occurred there had been 861 cases of pneumonia, or 1 case of empyema to every 8 or 9 cases of pneumonia. The pleural fluid effused during childhood showed a marked tendency to become purulent, and the younger the child the more pronounced was this tendency. The effusion in a child under 3 years would almost certainly be of a purulent character. In 59 cases of pleural effusion in such young children the fluid was purulent in 53. The tendency of the fluid to become purulent gradually lessened from 3 years till the age of 10, when the formation of a serous effusion was usual in the great majority of cases. Of 149 cases of pleural effusion the following was the analysis:—

Under 6 months of age	3 cases, all purulent.		
Between 6 months and 12 months	9 „	8 „	1 serous.
„ 1 and 2 years	26 „	24 „	2 „
„ 2 „ 3 „	21 „	18 „	3 „
„ 3 „ 5 „	23 „	18 „	5 „
„ 5 „ 10 „	57 „	27 „	30 „
Over 10 years	10 „	1 „	9 „

The following shows the percentage distribution of infecting organisms: In 53 per cent. the pneumococcus was present alone; in 16 per cent. the streptococcus was present alone; in 14 per cent. the pneumococcus and streptococcus were mixed; in 3 per cent. the staphylococcus and streptococcus were alone; in 1 per cent. staphylococcus and pneumococcus were mixed; in 2 per cent. the staphylococcus, pneumococcus, and streptococcus were mixed; in 3 per cent. the tubercle bacillus and streptococcus were alone; and in 6 per cent. there were no growths. As to the causation of empyema in children, while admitting the occurrence of primary forms due either to cold or injury, Dr. Dunlop believed that in the majority of cases the condition was secondary. In only 7 per cent. of the cases was a history of lung or other antecedent history lacking. In the majority of cases the effusion either occurred with or followed lobar pneumonia; and then the fluid was invariably purulent. Empyema in his experience was much less frequently associated with bronchopneumonia. It frequently developed after scarlet fever, measles, or whooping-cough, and occasionally after influenza. Any suppurative process, such as purulent arthritis or osteomyelitis, might account for it, and in young infants septicæmia was a common cause. In striking contrast to empyema in the adult, a very small proportion in children was due to tubercle. Of his cases, lobar pneumonia accounted for 69 per cent.; infectious diseases, 11 per cent.; broncho-pneumonia, 5; suppurative processes, 3; tubercle, 3; influenza, 2; causes unknown, 7. In most instances the effusion in cases of pneumonia occurred within a few days of the crisis. Sometimes the symptoms heralding the onset of empyema were acute and violent; in others they were insidious and indefinite. He cordially agreed with the writer who said that latency in pneumonia was synonymous with carelessness in the physician. The child was often sent into the hospital with a diagnosis of atrophy or miliary tuberculosis, and the general appearance went far to confirm such a diagnosis. In six of his cases convulsions were the earliest manifestation of empyema, while the other symptoms in the order of frequency were fever, cough, vomiting, quick breathing, sweating, restlessness, and delirium. In older children, and especially after infectious diseases, the foregoing symptoms were less pronounced, but the child gradually assumed a languid appearance, suffered from a short paroxysmal cough, and emaciated rapidly. As regarded sex, 53 were boys and 45 girls. The left side was involved 45 times, the right 39, which was not at all the usual proportion or what would have been expected from the frequency with which left-sided pneumonia occurred. Both sides were involved in four cases. The amount of fluid varied greatly both in quantity (¾ oz. to 40 oz.) and in the time it took to collect. In some cases he found one side of the chest filled with pus in a few days. A number of symptoms were very suggestive of empyema. First, in almost every case the child looked seriously ill, had an anxious, pinched, and frightened expression, and was profoundly anæmic. The face was earthy or yellow in colour with sometimes puffiness under the eyes. There was a very rapid and sometimes extreme emaciation. When a child was suffering from marasmus he invariably excluded three diseases—viz., tuberculosis, congenital syphilis, and empyema—before concluding that the diagnosis was correct. There was usually some cough, either suppressed or paroxysmal, and the breathing was quick, but never so quick as in pneumonia. Even when the pleura was full of pus there might be little real dyspnœa. The temperature was usually raised from 3° to 4°, and it might be very high or subnormal. In ten of his cases it was either normal or subnormal during the whole period of observation. Clubbing of the fingers might be observed when the empyema had lasted a long time. When the fluid was present there was generally a leucocytosis of from 20,000 to 30,000. His experience did not bear out the statement that diarrhœa might be present. Clinically, whenever absolute dulness of a board-like character at the base with a boxy percussion note at the apex was noted a pleural effusion should be suspected. The sense of resistance to the percussing finger also was of great value. It was quite common to get loud tubular breathing over a purulent effusion in the child—a misleading point to those accustomed to investigate empyema in the adult. Vocal fremitus was of little help, but displacement of the heart's apex was a very valuable aid in diagnosing fluid in the chest. It might be found in the epigastrium, or even as far as the right mammary line. The complications of empyema were generally due to further pneumococcal infection, and the commonest was purulent pericarditis, present in 40 per cent. of his fatal cases. This complication, often altogether undiagnosed during life, for friction was seldom if ever detected, should always be suspected if after draining the pleura freely the child continued ill with a rapid pulse. Purulent meningitis and peritonitis also occurred, but not suppurative arthritis or general septicæmia. Diagnosis was often difficult without the aid of an exploring needle; it might have to be passed repeatedly before the collection was reached, and even then if the fluid were thick it might not pass, or large masses of lymph might block the lumen. It was often said that a hectic temperature indicated pus, but he had found as high temperatures in serous as in purulent cases. The prognosis of pleural effusion was difficult, as the mortality was largely determined by the cause and duration of the illness and the age of the child. In the 98 cases there were 20 deaths, or 19 per cent. Under 2 years the prognosis was very grave; in 30 cases he had 11 deaths (36 per cent.). After 2 years 68 cases with 9 deaths (13 per cent). With a double effusion, of 4 cases only 1 recovered. Pneumococcal cases over 2 years almost invariably recovered, but in streptococcal and mixed infections the prognosis was not nearly so good. Tuberculous empyema was fortunately rare in the child, but the prognosis was not nearly so grave as in the adult. Pus in the pleural cavity should be evacuated as soon as diagnosed, for if the drainage was good and sepsis avoided the risks of complication were greatly diminished. In most cases any attempt to relieve the effusion by aspiration was a dangerous waste of time, and it was not very efficient. Where the exploring syringe had drawn off merely turbid serum aspiration had often given him good results, and it should be tried in very young infants unable to stand a serious operation. Aspiration was useful also, when the effusion was very large, to draw off a quantity of pus the day previous to operation. It did not draw off all the pus; large masses of fibrin were left, and no drainage being possible resection was usually needed later. In operation either resection of the rib or simple incision of the pleura formed the choice. The former gave better drainage and less risk of sepsis but was a more serious operation. Simple incision was better for young infants. Of his cases, 8 were aspirated, with 1 death; 61 were resected, with 14 deaths; and 29 were incised, with 5 deaths. The main danger of the operation being syncope and death from the anæsthetic, local anæsthesia was preferable in young infants. The incision, 2 or 3 inches long, should be made in the sixth interspace in the mid-axillary line. To avoid syncope the pus should be allowed to escape very gradually. The tube might be removed in 7–10 days and should seldom be retained longer than 3 or 4 weeks.—Professor F. M. CAIRD alluded to the value of Truby King's suggestion of having a few drops of sterile water in the exploring syringe, so that if the needle became blocked a few drops could be injected and then withdrawn. If pus were present it could easily be detected in the syringe.—Dr. JOHN THOMSON said that he had never been able to hear friction in pericarditis in children. He attached importance to the child's general health in determining whether a pleurisy were serous or purulent. If the child was healthy there was much less risk of empyema than if it were weak. As a preliminary measure he favoured aspiration, and he had had two or three dozen cases where a single aspiration had been sufficient to effect a cure.—Dr. ALEXANDER GOODALL had found auscultation very misleading in empyema in adults, and bronchial breathing was often marked and loud over an effusion.—Dr. DUNLOP replied.

Mr. D. P. D. WILKIE read a communication entitled "Observations on the Pathology and Etiology of Duodenal Ulcer," with an epidiascope demonstration. He said that the credit of recognising that this ulcer was of frequent occurrence was due to W. J. Mayo, Moynihan, and Mayo Robson. He wished to demonstrate certain facts gained chiefly from the post-mortem room. During the past three years he had investigated the condition of 490 cadavers, and he had met with 41 cases of duodenal ulcer, and in only 6 of these had the ulcer any direct connexion with the death of the patient. In only 6 cases had a diagnosis of duodenal ulcer been made before death, and all of them had been operated on. In one or two cases where a chronic ulcer had been found it had caused during life none of the typical symptoms. Such "silent" ulcers might attain considerable size and cause death from hæmorrhage or perforation without producing any noteworthy symptoms. The subjects of these "silent" types of duodenal ulcer were generally old people with arterio-sclerosis. The "syndrôme pylorique" described by Soupault and resembling the Moynihan's symptom-complex of duodenal ulcer might be, but was not invariably, associated with a duodenal ulcer. It appeared to be the clinical expression of an irritable condition of the pyloric musculature favouring spasmodic contraction. It might, however, be associated with an ulcer on the gastric side of the pylorus. *Morbid anatomy:* In the 41 cases the lesions were situated on the first part of the duodenum and with two exceptions within one inch of the pylorus. In 9 cases the ulcer was on the anterior wall from half to three-quarters of an inch beyond the pylorus; in 12 it was on the posterior, and in other 12 there was an ulcer on both anterior and posterior walls directly opposite one another (the so-called "kissing ulcers" of Moynihan). In 5 cases the ulcer was at the upper part or roof of the duodenum just beyond the pylorus, whilst in one female case a large ulcer occupied the lower wall of the duodenum, extended to the posterior wall, and invaded the pylorus. In 21 cases there was but one ulcer, in 16 two ulcers, and in 4 more than two ulcers. In some of the cases where a fair-sized ulcer was found on the posterior wall no suspicion of its presence had been aroused by a careful examination of the unopened gut. The impression left by such cases was that this type of ulcer must be frequently overlooked at operation, and the question arose whether the duodenum should not be opened in doubtful cases. In 5 cases besides the duodenal lesion one or more gastric ulcers situated on the lesser curvature some distance from the pylorus were found. Of acute and chronic ulcer it was not so easy to speak with assurance as in the case of gastric ulcer. With ulcers on the anterior wall, many which from the outer surface of the intestine showed evidence of chronicity closely resembled acute ulcers when viewed from the mucous aspect. Chronic ulcers of the posterior and postero-superior walls were usually more easily recognised, resembling as they often did the large crater-like ulcers of the stomach. The essential factor for the formation of a duodenal as of a gastric ulcer, was that a portion of the mucosa became so devitalised that it might be digested and leave a breach of surface. This devitalisation might be brought about by (1) the lodging of an embolus in an arteriole of the duodenal wall; (2) venous embolism; (3) the circulating of toxin in the blood, causing a degeneration not only of the lining epithelium of the bowel but of the endothelium of the capillary blood-vessels, so that small hæmorrhages took place and determined local areas of lowered resistance; and (4) reflex nervous spasm of the vessels or of the muscularis mucosæ causing small hæmorrhages into the mucous membrane. He discussed these causes at length, and said that toxic degeneration or necrosis of the mucosa or of lymph follicles of the duodenum followed by digestion was probably the most frequent cause of acute ulceration. The source and nature of the toxin might vary widely; thus the products of tissue autolysis circulating in the blood caused degeneration in the parenchyma of various organs, and in the stomach and duodenum digestion of the devitalised tissue followed with the formation of ulcers. In two of his cases death resulted from widespread superficial burns, in one case five and in the other 12 days after the accident. Mr. Wilkie was convinced that some definite relationship existed between morbid conditions in the lower bowel and duodenal ulcer. The relationship between them was not clear, but he was inclined to think that the ulcer was due to a combined action through the blood and through the autonomic nervous system. Rössle had been struck by the frequent association of chronic appendicitis and duodenal ulcer. There was some evidence to show that toxic absorption from the colon had a definite vago-tonic influence. The periodicity of the symptoms of duodenal ulcer, the effect of worry, over-fatigue and chills, and vaso-motor disturbances in determining the onset of a fresh attack all pointed to the importance of the nervous factor in duodenal ulcer. After discussing the site of the ulcer and the sex incidence he drew the following conclusions: 1. Duodenal ulcer is a disease of frequent occurrence and one which often passes unrecognised. 2. Although as a rule readily recognised, a chronic ulcer may occasionally exist and give rise to none of the characteristic symptoms, the first evidence of such a "silent" ulcer being sometimes its perforation. 3. "Silent" duodenal ulcers are met with most frequently in the subjects of arterio-sclerosis and are found for the most part on the posterior wall. 4. Some toxic or irritative factor, usually within the abdomen and most often associated with the colon or appendix, is found in a large proportion of cases. 5. Probably many acute duodenal ulcers are primarily follicular ulcers from the breaking down of inflamed lymph follicles. 6. Whatever be the primary cause of a gastric or duodenal ulcer, spasm of the muscular coats of the viscus is an important factor in determining its chronicity. 7. The situation of the opposing ulcers on the anterior and posterior walls on the boundary zone of the areas supplied by the anterior and posterior branches of the supraduodenal artery suggests that a common vascular deficiency, rather than a contact infection, accounts for the peculiar tendency to chronicity and recurrence. 8. This vascular deficiency may be due to arterio-sclerosis, but probably it is usually due to spasm of the muscular coats of the duodenum, induced by a slight local anæmia consequent on strain on the supraduodenal vessels, this muscular spasm being favoured by the increased vago-tonus and the irritable condition of the autonomic nervous system which exist in such cases. 9. The sex incidence of duodenal ulcer is to be explained on anatomical grounds. The relatively high pylorus and short fixed duodenum of the male allow of its vascular supporting ligament, the hepato-duodenal ligament, being exposed to strain, which in the female with her relatively low pylorus and lax duodenum is borne by the left border of the gastro-hepatic omentum and lesser curvature of the stomach. 10. The fixity of the male duodenum further predisposes to kinking at the first duodenal angle, and thus to an unduly long exposure of its first part to the acid chyme from the stomach.—Professor **CAIRD** said that the late Professor Hamilton, of Aberdeen, believed that there was no relation between burns and duodenal ulcers, and personally he had found no such association.—Professor **WILLIAM RUSSELL** alluded to the relation which existed between conditions in the lower part of the intestinal tract and duodenal ulcer. He was glad to know that Mr. Wilkie did not believe in the view of embolism as a cause of duodenal ulcer. He had taught for long that local spasm caused anæmia and this led to acute erosion. Both duodenal and gastric ulcers were very frequently associated with hyperchlorhydria. Duodenal ulcer was very difficult to diagnose if there was hyperchlorhydria present, and one ought never to diagnose it unless there was melæna or occult blood present.—Professor **ALEXIS THOMSON** thought we should be chary in accepting the theory of the bands in connexion with the stomach and duodenum as causal agents as well as about the condition of the lower bowel. The toxic factors which underlay the production of appendicitis might be the cause of duodenal ulcer also. The stasis of the bowel in women rather was antagonistic to the sex relationship of the disease, and the ulcer was often present in young men who had no intestinal stasis.—Dr. **D. CHALMERS WATSON**, Mr. **J. WHEELER DOWDEN**, and Mr. **J. W. STRUTHERS** also took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Wassermann Reaction.

A MEETING of this section was held on May 1st, Dr. **J. B. COLEMAN**, C.M.G., the President, being in the chair.

Professor **E. J. McWEENEY** read a communication on Experiences with the Wassermann Reaction. He had invariably carried out the original technique with the exception that he used a non-specific antigen and adopted the quantities and general procedure laid down by M'Intosh and Fildes in their valuable text-book on syphilis. The number of cases he had tested so far was 240, of which 182 were available for statistics. From the Lock Hospital he had examined 54, of which 47 were undoubtedly syphilitic. The percentage of cases in which the reaction gave results in accordance with the clinical aspect was 91·3. Of the 7 non-syphilitic cases, all reacted negatively to the test. From the Mater Misericordiæ Hospital 46 cases were available, of which 37, or nearly 85 per cent., gave reactions in accordance with the clinical aspect. From the Richmond Asylum he had tested the serum of 35 cases, of which 26 were definitely diagnosed as general paralysis, 5 were looked upon as certainly not of that nature, and 4 were regarded as suspicious or doubtful. Of the 26 clinically certain cases, 19, or 74 per cent., gave a strongly positive reaction, 4 were negative, and 3 were doubtful to the test. For reasons mentioned two of the latter ought to be regarded as positive, raising the number of accordant positive results to 81 per cent. All the cases (5) in which general paralysis was clinically excluded gave a negative result. The speaker had also examined a number of cerebro-spinal fluids, and found a positive reaction in nearly all that were diagnosed as general paralysis of the insane. With regard to the globulin-content of these fluids he had found the Nonne-Apelt, "Phase I.," test the most satisfactory, provided a time limit of three minutes was observed, and the fluid was mixed with the ammonium sulphate, not superposed, as recommended by Ross and Jones. With the Noguchi (butyric acid) method he had obtained, too, many positive results. Out of 49 cases sent in from various hospitals and private practitioners there were only four in which the result of the Wassermann test was not reconcilable with the clinical aspect. The speaker then described the technique. He mentioned the several pitfalls which the method presented for the inexperienced operator, more especially that due to "cutting the hæmolytic system too fine," with the result that complete hæmolysis did not occur in the tube without antigen. He discussed the value of various antigens, and stated that in his experience alcoholic extract of sheep's heart, without added cholesterin, worked quite well, and kept almost indefinitely. He drew attention to the superior delicacy of the method of Browning, Cruickshank, and M'Kenzie, which had given a positive result in a congenitally syphilitic child, when the ordinary technique was negative. He referred to comparative tests which he had done with active serum by Stern's and Fleming's methods, and also with the precipitation methods of Elias and Neubauer, and of Herman and Perutz, but would not place implicit reliance on any of them in the absence of a proper Wassermann test. He drew attention to the great prevalence of syphilis amongst imbecile children, and also amongst gynæcological out-patients, as shown by the Wassermann test in the hands of members of the Glasgow school, and stated that one of his objects in coming forward with the paper was to point out the necessity for systematic investigation on similar lines amongst the same classes in Ireland.

Dr. J. T. Wigham said that the experience in the Trinity College Laboratory did not enable him to make any more definite pronouncement on the subject than that made in the paper. He commenced with Birt's method, which he considered the easiest, and which had been found in the army to give satisfactory results. The method differed essentially from the original; the antigen was very much the same as in the original, but the complement was the patient's complement, the cells were the patient's cells, and the amboceptor was from the rabbit; hence the results were not so certain as if the original reaction was used. The Fleming reaction had now been adopted in his laboratory. As it was a method in which inactivated serum was not used it had been found to be too sensitive in some respects, giving a positive reaction in some cases where the original method would have given a negative; it had, however, the advantage that it did not require much blood. He referred to the difficulty of getting practitioners to send a sufficient quantity of blood. He considered that in any case in which human complement was used it was necessary to leave the serum on the clot. Having latterly controlled results with the original Wassermann test, working with two antigens, it was found that Fleming's method was on the whole satisfactory.

Dr. Adrian Stokes said he considered that the results of treatment were still better shown by the Wassermann test. Patients were seen with secondary syphilis giving a strong positive reaction, and after three or four weeks' treatment the reaction might be observed shading off. He considered that a negative reaction was the ultimate proof as to whether a patient had any active syphilis in his body or not, and no patient who ever had syphilis should be satisfied until he gave a negative reaction, and although tertiary cases might take an enormous amount of salvarsan before a negative reaction was produced, yet he thought it was worth trying to bring it about. Referring to deafness and blindness, the result of syphilis, he thought that in some such cases this was brought about by syphilitic neuritis, and suggested the advantage of lumbar puncture. As to the question of heating the serum, he thought that the reason why it was important to do this was that it produced destruction of the non-specific fixing bodies. He suggested that it was unnecessary to kill the guinea-pigs. He had succeeded in getting as much as 10 c.c. from the heart without killing the animal, and after 20 days' time it gave a complement as good as at the beginning. In his own tests he always titrated the complement and the antigen, and having done this, two hæmolytic doses of each were used. Two different antigens were used also, one more active than the other, which helped in the reading. The tendency to use more than two antigens was on the increase. He pointed out that the cerebro-spinal fluid tests depended upon the quantities used. If large quantities were taken there was more likelihood of getting reaction than if smaller quantities were used. He was at present using 0·1 serum for diagnosis, and 0·5, 0·4, 0·3, 0·2, 0·1 of cerebro-spinal fluid.

Mr. H. Moore said it was not sufficient to treat a patient until he gave a negative reaction, and then tell him that he was cured. The patient should come back several times at intervals and have the test done. In cases where secondary syphilis was well established a patient might give a negative reaction, but if tests were done every two or three months it would be generally found that within one year he would give a positive reaction again. This he considered the time to commence a second course, and in his opinion if a second course was then carried out it was improbable that a recurrence would take place. In many of the cases of secondary syphilis that he had seen a positive reaction was found again in about nine months, and when the patients had got another course they then remained negative. He referred to the experience of negative reactions in cases of tertiary syphilitic lesions of bone.

Dr. W. R. Dawson said that although it had recently been discovered that in cases of mental defect some 66 per cent. gave a positive reaction in England, he did not think that a similar state of things existed in Ireland. He thought it would be found that, except in a few of the larger towns, there was very little syphilis amongst the mental cases in Ireland, and pointed out that there were very few paralytic symptoms. He was fairly convinced that throughout Ireland syphilis had very little to do with insanity or any other mental defect.

Professor McWeeney, in reply, said that he did not wish to take up the position of denying that simplified methods, such as Birt's and Fleming's, had no value, but he leaned to the view that the original technique should be adhered to whenever possible. Using a Fleming technique with several strengths of antigen it seemed to him as complicated as the original method. He would feel anxious about giving a diagnosis on the result of any simplified method. He agreed that it was advisable that lumbar puncture should be done more frequently in nervous cases. He agreed with the remarks of Dr. Dawson that the examination of mental or nervous patients in Ireland would not reveal any great prevalence of syphilis, but he would nevertheless like to have this placed beyond doubt. The statement regarding tertiary bone lesions giving a negative reaction agreed with his experience.

Medico-Psychological Association of Great Britain and Ireland.—A meeting of the Northern and Midland Division of this association was held on April 30th at the West Riding Asylum, Menston.—Dr. S. Edgerley, who presided, read an interesting paper on the Alleged Increase of Insanity, taking a very optimistic view of the subject. He stated that his paper only dealt with the north part of the West Riding, the area, consisting of manufacturing cities and towns and agricultural districts, from which Menston Asylum draws its patients. Statistically the West Riding occupied a very favourable position as regarded its sanity. The first point to be settled was: What was meant by an increase in insanity? It might signify an increase in the total number resident, an increase in the number of admissions, or an increase in the annual number of first admissions —the last would appear to be the really important aspect of the question. *Are people becoming more liable to insanity?* had also to be considered. He thought the total increase in the asylum population depended on the relation of the output to the intake; they would therefore not see a reduction until they could reduce the intake and increase the output. Can anything be done to diminish the incidence of insanity? Four great causes were being grappled with—poverty, ill-health, excessive indulgence in alcohol, and preventable contagious diseases. He thought it was possible to exaggerate the influence of hereditary predisposition. His conclusion was that in that part of the West Riding, whatever bald statistics might appear to show, insanity was not in the real sense increasing; indeed, there was every reason to hope and expect that it would decrease.—An interesting discussion followed in which many of the members took part. The main points were: Was epilepsy increasing or decreasing? Did the decreased infantile mortality mean an increase of insanity, or were we saving children for them to become insane later? One member considered that the tendency was for insanity to increase, in view of the reduced number of children more especially in middle-class families. —Dr. Bedford Pierce then opened a discussion on the Treatment of Incipient Insanity. This, he said, had to be considered under two main heads—viz., in the case of those able to pay, and those unable to pay for their treatment. He thought that some new kind of institution would be required; that cliniques attached to hospitals would be advisable; that coöperation of hospitals, boards of guardians, &c., would be necessary. Institutions would have to be equipped with up-to-date methods of treatment, and suitable means of employment and recreation would have to be found for the patients. How to carry out all this would be difficult, as the capital expenditure would be a serious item, and then, would the public support it? He, however, thought that something should be done in the way of erecting suitable sanatoriums for the treatment of incipient cases.—Many interesting points were brought out in the discussion which followed.— A vote of thanks was accorded to Dr. Edgerley for his hospitality and for presiding.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 30th, Mr. W. S. Kerr, the President, being in the chair.—Dr. R. Gordon opened a discussion on Malingering under the Insurance Act. He said that many medical men seemed to think that there was practically no such malingering, but Friendly Society and insurance officials asserted that it was rampant. It certainly looked as though there was a considerable amount, for a Departmental Committee had been appointed to inquire into it. Under the old Friendly Society system a certain amount of malingering existed, but as every man took a personal interest in his lodge or society anyone found shamming was very soon brought before the club. At that time 6,000,000 persons belonged to societies. Now over 14,000,000 were insured, and in the competition for members many thousands of weakly men and women were enrolled who really should have been deposit contributors. Many of these were of poor physique and far below the normal standard of health, and as unearned increment had a fatal fascination for most people, it was not surprising that many took advantage of the slightest illness to "go on the State." Then many men, in addition to being insured, also belonged to one or more clubs, and were actually drawing more money than when working, so that the desire to return to work was not so great as it would otherwise be. The sickness and disablement figures on which the Act was based varied from 0·92 week per annum at 16 years of age to 6·31 at 65—the period covered by the Act of 1911. In one of the large societies, consisting of men between 16 and 65 years of age, in Sheffield, and comprising steel workers and labourers, cutlers, grinders, and silver workers, 32·92 per cent. were ill. The average duration in proportion to the whole number was 6·87 days, and the amount paid was 9*s.* 6·59*d.* This compared very favourably with the actuarial allowance of 9*s.* 6.*d.* Of men from 65 to 70 years, 41·32 per cent. were ill for an average period of 13·28 days, and the amount paid was 11*s.* 7·16*d.* Of women, 37·104 were ill for an average period of 10·08 days, and the amount paid was 10*s.* 7·72*d.*, which was very much more than the actuarial allowance of 6*s.* 11½*d.* These figures were also borne out by a large industrial insurance society, where the men received 8*s.* 0·009*d.*, and the women 11*s.* 0·205*d.*; also by the Manchester Unity, where the actual payments to men were £196,628, and the actuarial estimate £213,196. For women the amount paid was £48,303, the estimate being £42,292. These figures, Dr. Gordon said, went to show that there was very little malingering among men, and that if the giving of certificates was more strictly regulated there would be less still. So far as women were concerned the figures showed that the actuarial estimate was entirely wrong, and that there was much more sickness among them than was estimated.—In the discussion which followed there was a consensus of opinion that there is very little malingering under the present Act.

HARVEIAN SOCIETY.—A meeting of this society was held on April 30th, at the Stafford Rooms, Tichborne-street, W., Mr. J. Jackson Clarke, the President, being in the chair.—Mr. Ernest Clarke read a paper on Some Errors in Diagnosis and Treatment in Ophthalmic Practice. He first spoke of epiphora, stating that mistakes were frequently made by omitting to examine the position of the lower punctum. The slight ectropion which often appeared after middle life caused the punctum to look up, and made it incapable of "sucking up" the tears. The specific for this was slitting up the canaliculus, putting in a nail-head style, and making a gutter in the ocular lip for it to lie in. He recommended West's operation for lacrymal obstruction in bad cases of chronic dacryocystitis. He spoke of the frequency with which early iritis, cyclitis, and small corneal abrasions were missed, and dwelt upon the importance of alimentary toxæmia as the cause of iritis. Eye strain was generally due to a small amount of astigmatism, and might be the cause of almost any functional nerve trouble. It should be insisted upon that the examination should be made with the aid of a cycloplegic. It was a most dangerous and useless placebo to order +·50 sph. for children to use for school work. If astigmatism were present glasses should be worn always. Myopia should be corrected fully except in very high degrees. He advocated *invisible bi-focal glasses* for cases of presbyopia complicated by other errors. From an examination of over 3000 patients after correction of their refractive error he proved that the average accommodation was from 1 to 1½ dioptres higher than was stated by Donders 50 years ago. He again emphasised the importance of intestinal stasis as a cause of presbyopia.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—The last meeting of the session of this society was held in the board room of the Great Northern Central Hospital on May 14th, Dr. T. Wilson Parry, the President, being in the chair. The election of officers for the next session took place, Dr. Ernest H. Shaw being elected President.—Dr. Parry then gave his presidential address entitled "Prehistoric Man and his Early Efforts to Combat Disease." He first sketched a picture of prehistoric man in his different stages from neolithic back to palæolithic and pre-palæolithic times. To this last-mentioned period must be attributed man's "beginning." Animals endeavoured to cure themselves when confronted with illness or injury; primitive man did likewise, only always a little more. Like an animal, primitive man would first of all lick his wounds, which after all was only a combination of modern fomentation and massage. Demonology was the origin of trephining. Dr. Parry gave details, from some 19 experiments he had performed on recent and dry skulls, how trephining was done in the Stone Age. This paper will shortly appear in a summarised form with illustrations in THE LANCET. It was profusely illustrated by lantern slides, and prehistoric implements and aboriginal trephined skulls were exhibited.

UNIVERSITY OF CAMBRIDGE.—The new School of Physiology erected by the Worshipful Company of Drapers will be declared open by H.R.H. Prince Arthur of Connaught at 3.30 P.M. on Tuesday, June 9th. Invitations to an "At Home" in the new building have been issued by Professor and Mrs. Langley.

Reviews and Notices of Books.

The British Journal of Surgery.

Volume I. 1913–14. With 486 figures, 4 portraits, and 9 coloured illustrations. Bristol: John Wright and Son. Pp. 748. Price 25*s.*

THIS new quarterly periodical, devoted entirely to British surgery, was noticed in these columns on its first appearance, and now the completed first year's volume lies before us. It is managed by an editorial committee of 35 surgeons, including representatives from all the great teaching centres of the United Kingdom and from the principal colonies. This committee, under the chairmanship of Sir Berkeley Moynihan, includes many of the leaders of British surgery, as well as a sufficient number of the younger men to ensure authoritative editing on the one hand and the energetic exploitation of new ideas on the other. Short notes of the work of a great teacher of surgery accompanied by a portrait appear in each number, and the present volume deals with Lord Lister, John Hunter, Abernethy, and Sir Astley Cooper. These articles, the letterpress of which is perhaps too brief, serve as a link between the progressive surgery of to-day and the pioneers of the past, whose work has laid the foundation upon which we are now building.

The greater part of the volume is occupied by original articles on surgical subjects, the majority being of a clinical character and the rest experimental and pathological. Among the most important of these may be mentioned the following: Renal Varix as a Cause of Symptomless Hæmaturia, by David Newman; the Influence of the First Costal Cartilage on the Incidence of Apical Phthisis, by Morriston Davies; Rupture of the Crucial Ligaments and Fractures of the Tibial Spine, by Robert Jones and Alwyne Smith; the Surgery of the Spleen, by Sir John Bland-Sutton; Intramural Extension of Rectal Cancer, by Monsarratt and Williams; Sellar Decompression, by Thorburn; an exhaustive article on Cleft Palate, by Goyder; the Congenital Enlargement of the Colon and Rectum, by Barrington-Ward; Radio-ulnar Synostosis, by Wilkie; a clinical study of cases illustrating the Growth and Repair of Bones, by Rutherford Morison; Experiences of Splenectomy in the Tropical Diseases of Egypt, by Owen Richards; an experimental study of 100 cases of Fracture of the Long Bones in Rabbits and Cats treated by Operative Methods, by Hey Groves; a study of Congenital Elevation of the Scapula, by Fairbank; an article on Massive Collapse of the Lung, by Pasteur; Typhoid Spine, by Elkin and Halpenny; Transplantation of the Fibula, by Bond; papers on Osteomyelitis, by Pringle and Evans; and a full account of Loose Bodies in the Knee-joint, by Anglin Whitelock.

The mere enumeration of these subjects will serve to indicate how wide has been the scope of the articles. Another series of articles of great value is that devoted to the critical review of subjects of theoretical and practical importance. In most of these articles the author has in addition to a review of the work of others made a substantial original contribution of his own observations.

A description of the methods employed by great masters of their craft is supplied in the form of visits to surgical clinics at home or abroad, and in this series some aspects of the work of Macewen, Tuffier, Lane, Lambotte, Horsley, Rutherford Morison, and Garré are noted with that fidelity in detail which conveys an accurate idea of the technique employed. One feature of special interest and novelty is the publication of "instructive mistakes." Short notes of rare or obscure cases also appear in each issue.

The journal as a whole appears to us to have removed the reproach that we have no British journal comparable to the annals, zeitschrifts, archivs, and revues of surgery which for many years past have formed the main organs for the publication of surgical research in foreign countries. Such a journal, managed and controlled by a large body of clinical and teaching surgeons, must do much towards bringing about a coöperation of workers in surgery in the advancement of their art. It provides, moreover, a suitable vehicle for the publication of special articles on research and experiment the nature of which makes them unsuitable for general medical literature.

In the matters of printing, illustration, and general get-up the new journal has been very well served, and if the present standard of originality and literary merit can be maintained its continued success is assured.

Acute General Miliary Tuberculosis.

By Professor Dr. G. CORNET. Translated by Mr. F. S. TINKER. London: John Bale, Sons, and Danielsson, Limited. Pp. vi.–107. Price 6*s.* net.

IN this small work, which has been translated in a pleasing manner by Mr. Tinker, Professor Cornet gives a summary of our present knowledge of general acute miliary tuberculosis. He considers that the breaking down of vascular tubercles which can be found in the walls of the big vessels fulfils all the conditions necessary for the origin of miliary tuberculosis. He makes the important statement that there is no proof of the existence of virulent bacilli in the blood of the phthisical patient or of the assumption that tubercle bacilli can multiply in the blood stream. He discusses the origin of the vascular tubercle, the methods of dissemination, and the causes thereof.

Chapter II. deals with pathological anatomy, and especially with findings of the vascular tubercles in the intima of the vein; also with the important question of mixed infections. Chapter III. deals with the symptoms and physical signs, and the author points out that the clinical picture is a much wider one than the anatomical picture. He gives illustrative cases showing that the disease is not always fatal. Though these non-fatal cases are rare, one in particular is beyond doubt, inasmuch as tubercle bacilli were found in the cerebro-spinal fluid, yet the case recovered. Discussing the difficulties and often the impossibility of making a certain diagnosis, the author deals with the more specific means to be adopted. Concerning the finding of bacilli in the blood, we agree that there is nothing definite known, and even acid-fast bacilli from distilled water have been mistaken for tubercle bacilli. He mentions the more trustworthy methods of finding the bacilli in the cerebro-spinal fluid and tubercles in the choroid, though an interval of one or two weeks must elapse after dissemination before these grow to macroscopic size. Such methods as diazo reaction, the viscosity of the blood, and the "complement-deviation method" are merely mentioned, and perhaps this is all that they at present deserve. The author considers that an X ray picture may often give important information as far as the lungs are concerned. An extensive bibliography completes the work.

We have found this book most readable and can recommend it as a summary of the subject with which it deals.

Biology, General and Medical.

By JOSEPH MCFARLAND, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College of Philadelphia. Second edition, thoroughly revised. With 160 illustrations. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 457. Price 7*s*. 6*d*. net.

IN reviewing this book in THE LANCET of Feb. 4th, 1911, on its first appearance, we were enabled to congratulate Professor McFarland on the admirable manner in which he had carried out his aim in providing first an excellent summary of the elements of biology for general readers, and, secondly, in the attention devoted to the more specialised medical aspects of the subject, so as to offer to general practitioners of medicine a broad but accurate survey of various fields of new knowledge. The former object naturally remains much *in statu quo;* but as regards the latter the present volume introduces such new matters as will bring the contents up to date and increase the usefulness of the book for medical readers particularly. The second half of the book, beginning with the chapter on ontogenesis, which is followed by chapters on conformity to type, divergence, structural relationship, blood relationship, parasitism, infection and immunity, mutilation and regeneration, grafting, senescence, decay, and death, gives a just summary of contending theories in language that will tend to afford a good bird's-eye view of the present status of knowledge and opinion. We note a slight blemish on p. 226, repeated elsewhere, where "fœti" is used as the plural of fœtus. Fœtus is, of course, fourth declension, and the plural, therefore, is also fœtus. But in English why not fœtuses?

The book is an admirable one, clearly written so as to be intelligible to those without much preliminary biological training, and well printed and got up.

A Practical Treatise on Medical Diagnosis for Students and Physicians.

By J. H. MUSSER. Sixth edition, revised by J. H. MUSSER, Jun. With 196 engravings and 27 coloured plates. London: H. Kimpton. 1914. Pp. 794. Price 25*s*. net.

THE sixth edition of the well-known treatise on medical diagnosis by the late Dr. John H. Musser has been brought out by his son, and fully maintains the high standard of excellence set by its predecessors. It has been necessary to make considerable additions to the last edition, which came out nine years ago, with the result that the book has been practically rewritten, while several of its sections have been materially shortened in order to keep the volume within reasonable bounds of size. The book is divided into two parts. The first of these deals with general diagnosis and contains four sections in which diagnosis is considered subjectively, objectively, from the physical point of view, and from the point of view of the laboratory. Part II., occupying the last 300 pages of the book, is devoted to the special diagnosis of the disorders of the various parts and systems of the body.

To point out the merits of this time-honoured text-book, the friend of many generations of medical students in America, may seem to be unnecessary. It is the work of an experienced practical physician, well arranged and clearly written, not encumbered by an abundance of references to the literature or to methods of physical examination whose only merit is their novelty. It gives an adequate account of the laboratory methods of diagnosis that are within general reach. The illustrations are well chosen, and there is a fairly good index at the end of the volume.

It may be cordially recommended to medical students and practitioners in search of a trustworthy book on medical diagnosis.

Technik der speziellen klinischen Untersuchungsmethoden.

Herausgegeben von TH. BRUGSCH und A. SCHITTENHELM. Part I. With 359 illustrations. Berlin: Urban und Schwarzenberg. 1914. Pp. 522. Price, paper, 36 marks per part.

THIS is the first volume of a large text-book on the technique of special clinical methods of investigation by many authors. It contains seven sections; the first of these, under the misnomer "hæmodynamics," devotes four of its five subsections to problems of hæmostatics. The fourth section gives a good account of German X ray methods; the fifth and sixth sections deal with bacteriological and histological methods of diagnosis generally; while the last section gives some account of various methods of optical investigation—polarimetry, colorimetry, and the like.

The book is well illustrated. It is not immediately apparent, perhaps, for what class of readers it has been written; for while it gives a general account of the increasing number of special methods of clinical investigation, it often fails to describe them with detail sufficient to enable a reader to give them a trial. It should, however, be of service in many clinical laboratories.

LIBRARY TABLE.

Problems of School Hygiene. Being a Report of the First Conference of Scottish School Medical Officers. Edited by W. LESLIE MACKENZIE, M.A., M.D. Aberd., LL.D.; and LEWIS D. CRUICKSHANK, M.D. Aberd., D.P.H. Edinburgh and London: W. Hodge and Co. 1914. Pp. 112. Price 2*s*. 6*d*.—The conference recorded in this volume took place on May 1st and 2nd, 1913, in Edinburgh, and was called at the instance of the officers of the Scotch Education Department. The interest of the conference will lie for the non-Scottish reader partly in its accentuation of the differences between England and Scotland, and partly in its full contribution to the discussion of physical training. In the field of medical inspection and in that of the segregation and special treatment of definite classes of defective children Scotland is, generally speaking, behind England. But there are some notable exceptions, and work on deaf children is being done at Glasgow of a particularly thorough character, and the holiday home provision for children at Edinburgh is very useful. On the physical training side of education, however, Scotland is giving a very definite lead through the instrumentality of the Dunfermline College of Hygiene and Physical Training. The work is of a very high standard, and in its effects may do as much to change the face of the school curriculum as will the application of open-air school ideas. The exactitude of the physical training work may be gauged from a summary of the more important points demanded from a student wishing to train as a teacher of this subject: "Age 18, height 5 ft. 4½ in., weight 9 st. Organs generally sound (these are specified in detail, of course, in the report), voice refined and of good round tone. Carriage and appearance good, not coarsely muscular. Evidence of good morals, self-discipline, general refinement, and temperamental fitness. The intellectual type preferred to the crudely muscular." One wonders if the time will come when analogous characteristics and qualities will be demanded from the ordinary teacher, and even, perhaps, from medical inspectors of schools. The speculation at least opens up an interesting vista into the future.

The Dietetic Treatment of Diabetes. By B. D. BASU, Major, I.M.S., retired. Fourth edition. Allahabad: Panini Office. 1913. Pp. 52. Price Rs. 1.8, or 2*s*.—This little book has been out of print for some time, but the author has not found it necessary to make any considerable alterations in the present issue. A summary of the statements of various authorities on the subject is given, and the author concludes with his own recommendations as to dietary, in which milk and cocoanut (i.e., coco) preparations figure largely, but exact directions as to quantity are not provided. The restriction, if not the total withdrawal, of meat, alcohol, tea, coffee, and cocoa (i.e., cacao) is advised.

How to Treat by Suggestion with and without Hypnosis. By EDWIN L. ASH, M.D. Lond. London: Mills and Boon, Limited. 1914. Pp. 104. Price 1*s*. net.—This is a little book detailing practical methods of suggestion, simple and hypnotic, intended, according to the author's prefatory note, solely for the medical profession. There are a few illustrative cases, and remarks on special indications, kinds of suggestions, and so on. In addition are reprinted four papers by the author from THE LANCET and other medical journals.

MISCELLANEOUS VOLUMES.

IN *Building By-Laws in Rural Districts* (London: P. S. King and Son. 1914. Pp. 66. Price, cloth, 1*s*. 6*d*. net; paper 1*s*. net) Sir WILLIAM CHANCE has had reprinted the texto f a Bill which passed through the House of Lords without opposition in 1906 for the reform of the building by-laws in rural districts, in the hope that the book may be the means of interesting persons concerned and of obtaining support for the British Constitution Association in its effort to get the Bill re-introduced into Parliament and passed into law. The Bill is accompanied by a revised code of building by-laws for rural districts, designed to be an improvement upon the existing rural code. The obtaining of the most practical code possible for rural districts, in which building was so long hampered by restrictions drafted to meet the requirements of urban districts, is a very important matter if any substantial progress is ever to be made in the provision of healthy dwellings for the rural working population, and the name alone of Sir William Chance in connexion with such a subject should secure the attention of all interested in it. The arrangement adopted enables easy comparison to be made between the proposed model by-laws and those of the existing code which are intended to be altered or omitted, and a paper on the whole subject read by Sir William Chance before the British Constitution Association is printed by way of introduction.——The Warburton Lectures of the Manchester University for 1914 consist of two *Lectures on Housing* (Manchester: At the University Press. 1914. Pp. 70) delivered respectively by Mr. B. SEEBOHM ROWNTREE and Professor A. C. PIGOU. Mr. Rowntree discusses the permanent causes of shortage, and suggests a survey of housing conditions, expansion of the minimum wage policy, the "decasualising" of labour, compulsory town planning with restriction of number of houses to the acre, increased transit facilities and improved powers for the acquisition of land, the free lending of money for building to public utility societies, the making compulsory of satisfactory housing in towns, and relief of the rates by the National Exchequer conditionally on the fulfilment by local authorities of the statutory duties. Professor Pigou holds it essential that some minimum standard of factory conditions, leisure, dwelling accommodation, education, medical treatment, and supply of wholesome food and clothing should be established, but varying in different communities as they are rich or poor, so that the lapse below this standard in any one of the conditions should call for intervention by the public authorities. The future erection of insanitary houses should be forbidden, and where such exist they should be amended or destroyed; overcrowding of rooms should be prevented by direct legislation, a statutory definition of minimum cubic space being allotted per head—he suggests 400 cubic feet, which he would reduce with reluctance to half in the case of children under ten. He cites the example of the late Miss Octavia Hill as regards the value of personal influence of landlord over tenant. He realises the difficulty of condemning unfit houses as one can prohibit the distribution of unfit food; the hardship of the latter is spread over the community, while that of the former falls exclusively on individuals. He discusses somewhat doubtfully the minimum wage, but urges State aid for the housing of the poor, a mode of bounty which should not depend directly on, or vary inversely with, the wages paid to the recipient—the bad feature of the Poor-law—but should vary directly with the quantity of the purchases.

Trials for murder often arouse intense excitement at the time among the large section of the public which revels in horrors; and however unwholesome this taste may be, the newspapers would be less than human if they failed to gratify it to the full, so long as the issue of life and death for the accused person remains in the balance. But every murder trial provides also an instructive study to the criminologist and the student of criminal law, and in almost all such cases there is something of permanent medical and scientific interest. These aspects may be overlaid at the moment by the more gruesome and sensational features, which alone appeal to the popular imagination; but in the long run they usually determine whether any given *cause célèbre* shall fade into forgetfulness as a nine days' horror or whether it shall be re-enacted some years later before the limited audience which supports the issue of some notable trial series. The trial of Frederick Henry Seddon and his wife for the murder by arsenic of Miss Barrow certainly possessed enough medico-legal and scientific interest to justify its inclusion in such a series. Nevertheless, the issue of Mr. FILSON YOUNG'S *Trial of the Seddons* (Edinburgh: William Hodge and Co. 1914. Pp. 420. Price 5*s*.) within two years of the Old Bailey proceedings, while the matter is still fresh in the public mind, rather suggests that a wider demand is expected for this volume than for some of its predecessors—an impression which is heightened by the editor's general treatment of his subject. Some of the medical and scientific evidence comes in for criticism of a not very authoritative kind, but this aspect of the trial was considered in a leading article in THE LANCET at the time, and no new light is now thrown upon it. Although he is clearly satisfied that Seddon was a repulsive creature quite capable of murder, Mr. Young seems dissatisfied with the severe methods of the prosecution and inclined to think that on the evidence a verdict should have been returned in favour of the male prisoner as well as of his wife. He maintains that there was room for reasonable doubt, and implies that Seddon should have been given the benefit of it. This view, which [illegible] shared by the Court of Criminal Appeal, colours th[illegible] and dramatic introduction and is seen here and there in footnotes.——In *Women and Crime* (London: T. Werner Laurie. 1914. Pp. 303. Price 6*s*.) Mr. HARGRAVE L. ADAM shows how in some human beings gifted with their full complement of senses the will to do evil gets the upper hand. He gives a somewhat sketchy account of notorious woman criminals, such as Maria Manning, Jeanne Daniloff (afterwards Weiss), Mrs. Goold, Gabrielle Bompard, Mrs. Dyer, the amazing Madame Humbert, and others. He is of opinion that secret poisoning by women is of far greater extent than is generally known, and says that he personally "knows several women who encompassed the deaths of their husbands against whom no steps were taken, because no steps could be taken." It is not clear whether Mr. Adam means that these ladies poisoned their husbands or removed them in some other way.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLVIII., No. 1. March 31st, 1914. Cambridge University Press. Pp. 108. Price 6*s.* 6*d.*—Douglas Cow in an article on Diuresis points out that there is a certain discrepancy between the results recorded by different observers of the diuretic effects of water and saline solutions. Most observers have found that the intravenous injection of saline solutions is followed by an increase in diuresis, no matter whether the solutions were hypotonic, isotonic, or hypertonic. Other observers experimenting also on unanæsthetised dogs obtained different results. It is agreed, however, that water given by the mouth produces an increase in diuresis, but the result of subcutaneous or intravenous injections is not so certain. The author has continued his researches on this subject, using (1) unanæsthetised dogs, and (2) cats anæsthetised with urethane. For dogs (female) a catheter was used, and the 10 minutes' output of urine ascertained by weighing. In unanæsthetised animals the diuretic action of a substance may be masked by reflex or other causes. The mucous membrane of the stomach, duodenum, jejunum, and ileum contains a diuretic substance, that from the duodenum being the most active. This diuretic substance can be extracted in water or salt solution either at room temperature or boiling, and the extraction is independent of the presence of acid, but the most active preparations have been extracted in acidulated salt solution at room temperature. These extracts are not destroyed by boiling, but they lose their activity on keeping. Intravenous injections of small amounts of normal saline solutions produce an immediate increase in diuresis; this increase is but transient, and is very small in amount. Intravenous injection of small amounts of extracts of gastro-intestinal mucous membrane produce (*a*) an immediate increase in diuresis, similar to that produced by injections of saline; and (*b*) a delayed increase, which is considerable in amount and comparable to the increase produced by giving water by the mouth to normal animals. This delayed increase is not produced by intravenous injections of physiological amounts of saline. The author is of opinion that there is sufficient evidence that the physiological process of diuresis depends not only on the integrity of the kidneys and circulatory system and on the introduction of a certain quantity of fluid into the organism, but also on the presence of a specific substance contained in the gastro-intestinal mucous membrane, which substance is, presumably, taken up by water during the process of absorption from the gastro-intestinal tract.—On the Nature of the Fundamental Activity of the Nerve Centres, together with an Analysis of the Conditioning of Rhythmic Activity in Progression, and a Theory of the Evolution of Function in the Nervous System, by T. Graham Brown. This is an important contribution to which we have already alluded in THE LANCET (May 2nd, 1914, p. 1267). At the present time the "spinal reflex" is generally regarded as the "functional unit" of the nervous system. The author does not subscribe to this doctrine. He has studied more especially the progressive movements of the limbs shown by cats in a state of greater or less marked narcosis—i.e., under the influence of a general anæsthetic. The conclusion is arrived at that the experiments suggest also that the functional unit is the activity of the independent efferent neurone; they further suggest that the primitive activity of the nervous system is seen in such rhythmic acts as progression and respiration. The spinal reflex is "of the nature of a distorted 'beat'" of the rhythmic progression phenomenon.—Hyperpnœa as a Result of Pain and Ether in Man, by A. L. Meyer. Experiments on animals have shown that hyperpnœa incident to prolonged stimulation of sensory nerves is followed by apnœa, and in many cases the dogs died of cardiac failure. Henderson has shown experimentally that ether is capable of producing a hyperpnœa and a subsequent fatal apnœa. The same result may be brought about by excessive artificial respiration. The author experimented on himself, producing a condition of "pain hyperpnœa." A clamp was placed on the end of the little finger and screwed up so as to produce a blue nail in two or three instances and a pain such as might be caused by a severe paronychia. The clamp was kept on from one to three minutes. Under such conditions a hyperpnœa is produced that can easily be measured. The alveolar CO_2 is diminished, and the respiratory quotient increased. To determine the effect of the incipient stage of etherisation on man a mixture of approximately 5 per cent. of ether and air was inhaled. In man "ether hyperpnœa" is produced in one minute when a suitable low concentration of ether is used. The amount of hyperpnœa varies in different persons, and with higher concentrations the breathing is diminished.—The Relation between the Size of the Propagated Disturbances and the Rate of Conduction in Nerve, by E. D. Adrian. The nerve was narcotised with alcohol dissolved in Ringer's fluid. It was found that the rate of conduction did not depend on the distance travelled by the disturbance, although the disturbance suffered a considerable decrement as it passed down the nerve. The rate of conduction in the narcotised area does not vary as much as 3·5 per cent. when the strength of stimulus is increased to seven times its threshold value. The author confirms the conclusion of Koike that the rate of conduction does not depend on the size of the disturbance.—The Antagonism of Curari and Nicotine in Skeletal Muscle, by J. N. Langley. The muscle was fixed in the chamber in Ringer's fluid, the fluid run off, and curari or nicotine solution added. The rectus abdominis and sartorius muscles of the frog were used. The order of study was (1) the effect of curari given before nicotine on the contraction caused by nicotine in the neural region of the muscle; (2) the effect of curari given before nicotine on the contractions caused by nicotine in the general muscle substance; (3) the effect of curari given after nicotine; (4) the effect of mixtures of curari and nicotine; and (5) the region of action. As to (5) the question is—Do or do not nicotine and curari, pilocarpine and atropine, and certain other poisons, produce their effects by acting on the nerve endings—i.e., on the terminal branches of the nerve fibre? This question is best solved by experiments *on animals* in which the nerve endings have degenerated. Both in the fowl and frog nicotine and curari in minimal doses produce their effects after complete degeneration of the nerve endings, and this result the author regards as satisfactory evidence that these two poisons act on something peripheral to the nerve endings—i.e., they affect a constituent of the muscle.

Schmidts Jahrbücher der In- und Ausländischen Gesamten Medizin. Herausgegeben von Professor Dr. H. LEO. Bonn: A. Marcus and E. Weber. Price 36 marks per annum in Germany; 42 marks in other countries.—The April number contains three original articles. In the first Dr. Kadner, of Dresden, gives abstracts and analyses of 63 recent contributions to various journals on the subject of the physiology and pathology of the digestive organs. Upwards of 140 cases of resection of the stomach for ulcer or carcinoma are referred to, many of them terminating in recovery. In one of these contributions Dr. Hindhede supplies evidence to the effect that unpolished rice is dietetically far superior to polished rice, and that bread made from sifted rye flour is more wholesome than white bread. In the second Dr. Robert Salus, of Prague, reviews 79 recent memoirs on the subject of senile cataract. In the third Surgeon-General Professor Widenmann, of Berlin, publishes the introductory portion—equal in length to 15 or 20 pages of THE LANCET—of a paper on Medical Experiences in the Balkan Campaigns. The remaining portion of the April number consists of about 70 large pages containing extracts from 377 contributions to periodicals, the subjects being classified under 16 headings, of which the first eight are as follows: (1) Anatomy and Embryology; (2) Physiology; (3) Physiological and Pathological Chemistry; (4) Microbiology and Serology; (5) General Pathology and Pathological Anatomy; (6) Pharmacology and Toxicology; (7) Roentgenology and Radiology; and (8) Internal Medicine.

RADIOGEN.

RADIUM PREPARATIONS

KEEP INDEFINITELY and are GUARANTEED of STANDARD STRENGTH

RADIOGEN DRINKING WATER (1000 Mache). As prescribed by Eminent Physicians in England and on the Continent.

RADIOGEN CAPSULES. (For Oral Administration.)

RADIOGEN TABLETS. (Used in the treatment of Diseases of the Mouth and Teeth.)

RADIOGEN PASTE. (For Dental Massage.)

STERILE RADIOGEN SOLUTION. (For Irrigation in Pyorrhœa Alveolaris.)

RADIOGEN COMPRESSES. (Permanently Radioactive.)

RADIOGEN EARTH. (For the preparation of Radioactive Mud Baths.)

RADIOGEN EMANATORIUM.

FOR INSTALLATION IN HOSPITALS, HYDROS, SANATORIUMS, AND NURSING HOMES.
Used in the treatment of
GOUT, RHEUMATISM, ARTHRITIS, NEURITIS, and CONCOMITANT AFFECTIONS.

See "BRITISH MEDICAL JOURNAL," February 4th, 1911, page 243.

CHAS. ZIMMERMANN & CO. (CHEMICALS), Ltd., 9 & 10, St. Mary-at-Hill,
Telephones—AVENUE 6637-9. **LONDON, E.C.** Telegrams—"ACIDOLAN, LONDON."

(Biomalt),

a Food which is very extensively recommended by Medical Men abroad, is prepared from high class barley-malt, with the addition of calcium-glycerine-phosphate, and is now obtainable in Great Britain at all Chemists and Druggists. Samples and literature may be obtained post free from the Wholesale Depot of "Biomalz,"

REGENT HOUSE, KINGSWAY, LONDON, W.C.

IN

IODINE THERAPY.

Activity of IODÉOL.

In the comparative study of the properties of *IODÉOL*, one is at once struck by the fact that whereas ordinary isotonic solutions of colloidal metals contain *only 0·20 gm. of metal per litre*, *IODÉOL* contains the same quantity *in each cubic centimetre.* One ccm. of *IODÉOL* is therefore *one thousand times as active* as the same quantity of the ordinary solutions of metallic colloids. The indications for the therapeutic employment of a colloid such as *IODÉOL* are therefore numerous.

IODÉOL is specific for ***Pneumococcal Disease: Simple Pneumonia, Infective Pneumonia, Broncho-Pneumonia, Pulmonary Congestion*** both in man and animals. It acts as a diaphylactic, germicide, and lymphagogue, liquefies the exudations, modifies the character of the expectoration, relieves cough and dyspnœa, and brings about defervescence within 48 to 72 hours. Mortality barely reaches 3%.

Drs. HERY, BLANC, PHILOUZE,
(Therapeutic Society).
Drs. MIETTE, BRUNET, BOURGEOIS,
(Int. Cong. Path., Paris.)

Intra-muscular injections of IODÉOL are painless; they should be administered in the gluteal region at the seat of election, a needle one and fifth inch long and one thirty-sixth of an inch in diameter being employed.

CAPSULES containing doses of 4 grains of electro-chemical colloidal Iodine perfectly tolerated. Ten **times more active** than iodides, yet never producing iodism.

LIQUID FOR EXTERNAL USE containing 50% colloidal Iodine (should never be injected). Used in the same way as tincture of iodine, but ten times more active. Never causes **burns** or **irritation,** does not colour the skin, and is absorbed extremely rapidly.

OVULES. Each containing 22 grains colloidal Iodine. ***ANTISEPTIC*** without **IRRITATION.**

IODARGOL

The specific of GONORRHŒA, Acute or Chronic. Painless Injections.

Full Particulars, Clinical Reports, Samples, &c.,

THE LANCET.

LONDON: SATURDAY, MAY 23, 1914.

Treatment by Radium.

IN a leading article in our issue of Jan. 17th last we referred to the ever-interesting question of radium and cancer. Our remarks then were prompted by the appearance in the lay press at that time of statements which we considered to be scarcely justified by known facts and not unlikely to cause grievous disappointment to many sufferers from malignant disease. The report of the Radium Institute for the year 1913, which we publish this week, is an interesting confirmation of the attitude we took up four months ago, and in our opinion provides the strongest possible argument for the necessity of observing extreme caution regarding the value of radium in the treatment of malignant disease. A careful study of the tables gives us many interesting points for consideration. During the year 972 cases were dealt with; of these, 112 were examined but not treated. Of the remainder there were about 490 cases of malignant disease, including 111 of rodent ulcer. Of these cases of malignant disease none are stated to be actually cured, although 50 are described as apparently cured and 183 as "improved." In a number of cases the results are not yet noted, whilst others received prophylactic treatment only. At first sight the figures may seem disappointing, especially to the whole-hearted radium enthusiast, but further consideration of the report reveals much that is encouraging.

In the first place it is the sound policy of the Radium Institute to decline to treat operable cases, and this is rigidly adhered to, except under most exceptional circumstances. Radium is thus used only as a last resort, and the fact that so many of these cases can be described as "apparently cured" is highly creditable to the work of the Institute. Time alone can show if any of these satisfactory results are permanent, and not until some years have passed without fresh manifestations of the disease could even the most favourable cases be described as "cured." A further reason for the necessity for patience in accurately estimating the results attained is furnished by the following statement taken from the report: "Little or no effect appears to be exerted in the prevention of metastatic deposits, though the treatment does not, at any rate, hasten their dissemination." The action of radium being thus a purely local one, its field of usefulness must be necessarily limited, and especially so in regard to the treatment of malignant disease. At the same time the improvements in methods and technique that have taken place are extending the useful applications of radium, some of them sufficiently remarkable to call for special comment. It has been observed, for instance, that some cases in which pleurisy depended upon carcinomatous invasion of the pleura have been greatly improved by radium, and after a preliminary paracentesis the further formation of fluid has been effectually prevented. In carcinoma of the uterus again most gratifying results are being obtained, and in inoperable cases these are far in advance of those obtained by any other known medical and surgical methods. Much inferior, however, are the results in cases affecting the moist mucous membranes, especially about the mouth and throat, but even here improved methods are holding out greater hopes of success. It is a curious fact, upon which we commented previously and which is borne out in this report, that cases apparently alike respond so very differently to radium treatment, and this applies also to the same variety of tumour affecting parts that are anatomically closely related. Cases affecting the uterus, bladder, and upper portion of the rectum do better than those situated nearer the sphincters. These and many other instances tend to show how many difficulties have to be overcome and how the technique of the applications has to be studied and modified to suit constantly varying conditions. All this means much work and time for proper elucidation and serves to prove that real advancement in radium therapeutics must necessarily be slow, and that the day when we can speak of radium as a *cure* for malignant disease is still a long way off. We venture to hope that the publication of this report will do much to steady opinion on this question, not only within the medical profession, but also among the public.

Turning to other aspects of this report, it is satisfactory to see that some progress has been made in dealing with mediastinal tumours. Naturally large quantities of radium are necessary, and thick filters and long applications are the order of the day, but the results are such as give promise of benefit. It is only when we come to the treatment of the non-malignant tumours that the medical superintendent of the Institute, Mr. HAYWARD PINCH, allows himself to make use of the word "cure" regarding the result of his treatment. The number of these conditions that are easily cured by radium is now very large, and the fact that it can be used effectively in places not favourable to operation constitutes one of its greatest triumphs. Another important feature of radium that seems now to be fairly well established is the anæsthetic effect exerted by it in certain superficial conditions attended with pain or irritation. Painful keloids, pruritus, and lichenification of the skin are among those which have done well under this treatment. With regard to the efficacy of the solution of the emanation, about which so many conflicting statements have been made, this report has not very much to say. Apparently, however, the indications are that in early cases of arthritis deformans, or in those in which the changes are periarticular, the administration of this solution yields favourable results, especially in patients under 40 years of age. Little or no improvement is to be looked for in cases in which the osseous and cartilaginous changes predominate, and the report distinctly states that much research work remains to be done before any accurate opinion can be formed as to the therapeutic value of radium emanation solution, or as to the manner in which these changes are brought about.

Sir WILLIAM RAMSAY, since the use of radium has become more general, has always recommended its application in the form of niton rather than as a salt of radium on the ground that in the latter case there is considerable risk of loss of the precious radium, while this method does not insure a continuous application, as, for example, through the night. As he points out in a paper which we publish this week, the production of niton from radium is continuous; it goes on night and day, and the radiating power of niton is 75 per cent. of that of the radium from which it is derived. Niton can be used at any moment when its "strength" is known accurately, and a curve can be sent to the user which will enable him to know exactly what he is doing when he applies the active material. Sir WILLIAM RAMSAY describes for this purpose the introduction of niton into appropriate forms of apparatus—e.g., tubes, bulbs, and hollow flat discs. The convenience and economy of the method are evident, and we agree that these practical suggestions are a further argument in favour of having a central institute where a large supply of radium is kept, and from which frequent "drawings" of niton can be made, rather than of parcelling it out in small quantities, and having to be contented either with weak doses or to wait long for a strong dose at considerable pecuniary sacrifice. In other words, the niton method of application provides for the supply of a standardised agent. Taken as a whole, the report of last year's work of the Radium Institute is a record that adds very much to accurate knowledge of the therapeutic value of radium; and the sober, judicial manner in which it is expressed will do much to inspire confidence in the future of radiotherapeutics.

The New Milk Legislation.

A NEW Milk and Dairies Bill was introduced into the House of Commons on May 12th by the President of the Local Government Board, Mr. HERBERT SAMUEL, whose speech was reported in our last issue. The text of the Bill is now available. Like its predecessors, its principal clauses are those requiring regulations to be made by the central department with regard to the inspection of cows, cowsheds, and milk-shops, the prevention of infection and contamination of milk, the mixing of milk with separated milk and other substances, and conditions of storage and transit. These regulations are to be based on an enlargement of the existing powers of local councils under the old Contagious Diseases of Animals Acts, but apparently they will in large measure be enforced by a new set of authorities—the county councils instead of the district councils—by means of a staff which, in addition to the medical officers of health, is to include veterinary officers and bacteriologists. One of the anomalies of the present position is the invasion of country districts by officers of the numerous urban authorities which have special powers under local Acts, enabling them to act at the country cowshed in the interests of the particular town which has the powers, but not to prevent the tuberculous or contaminated milk being distributed elsewhere. The Bill adopts a sound principle in making each authority responsible for the milk produced in its own area, but it also recognises the urban interest by enabling the authorities in the town to requisition action by the authorities in the country as a result of bacteriological or other sufficient evidence against the milk. Penalties are imposed on persons knowingly selling milk from diseased cows, and the medical officer of health will have powers to stop the supply of milk which is ascertained to be tuberculous. In practice it is evidently expected that the work of the local authorities under the Bill and the work under the orders relating to tuberculosis in cattle issued by the Board of Agriculture will be carried out together, and that the same veterinary officers who detect the tuberculous cows will be able to give the instructions necessary under the orders for the slaughter of the cows and for the payment of compensation, which is to be on a more liberal scale than hitherto. A clause in the Bill, which is developed in a schedule, will introduce a considerable change in the practice of dealing with adulterated milk. It has long been a disputed question whether milk should be standardised, for example, at a minimum of 3 or 3·25 per cent. of fat, if it is officially to be regarded as "genuine," or whether genuine milk may include any milk, however low in fat, provided it has not been tampered with after leaving the cow. The latter view is adopted in the Bill, and local authorities will be expected to accede to the request on the part of the milk seller to obtain samples of milk on delivery to him for comparison with the incriminated sample, and if necessary to go back to the farm. It is stated that this procedure has long been followed with success in some of the larger provincial towns, and that the trouble involved in tracing the real offender is justified by the results obtained.

The overwhelming case for national milk legislation needs no re-statement here; to readers of medical literature the occurrence of bovine tuberculosis in children and of outbreaks of infectious disease due to milk, and the relation of infantile illnesses to dirty or contaminated milk, are only too familiar, and it would be difficult to over-estimate the extent of essentially preventable disease which is thus habitually brought about. We are far from ignoring the comparative safety which may be obtained by the use of properly pasteurised milk suitably prepared and delivered, or of dried milk, or of sterilising processes such as the electric treatment to which Professor J. M. BEATTIE has recently drawn attention. The movement in favour of obtaining "certified" milk prepared with special precautions also deserves every encouragement, and the official regulation of "certified milk" might well be included in the new legislation. But none of these measures suffice to meet the main demand. The ordinary householder does not want to buy special varieties of milk, or care to be offered milk graded according to its degree of bacteriological purity. He expects that what is sold to him as milk should be a reasonably sound commodity which he can consume, without cause for serious apprehension, in the raw state in which he generally prefers it. Though this needs an effort, it is by no means an impracticable demand to meet. The proposals of the Government Bill for the purpose will depend for their success, partly on the nature of the regulations made, and still more on the administration of the authorities, both central and local, which have to carry out the new policy. The appointment of a considerable veterinary staff as whole-time officials acting with the local public health departments must obviously form part of the intended administration. These veterinary officers will be needed not only to detect bovine tuberculosis and pay compensation to the owner of the slaughtered animal, but to advise the dairy farmer how to remove the conditions which favour bovine infection, and to enforce regulations made with that object.

It is believed that Mr. SAMUEL, warned by the fate of previous Bills, has taken great care to ascertain the way in which different branches of the milk industry will be affected by the proposed legislation and has made substantial efforts to meet their suggestions and anticipate objections. On considering the Bill as a whole, those who have so long been pressing for reform from the side of public health may perhaps consider that concession has gone too far in this direction. But much may be sacrificed for the prospect of an administrative scheme which on its inception would receive the cordial support and assistance of the majority and the best of those engaged in the industry, and which, in the case of all but those whose record shows them undeserving of consideration, would bring about progress by coöperation rather than by coercion.

DINNER TO MR. WILLIAM LANG.—On Thursday, June 25th, Sir Henry Morris, Bart., will preside at a dinner given to Mr. William Lang on his retirement after 33 years of active duty on the honorary staff of the Middlesex Hospital. The dinner will be held at Pagani's Restaurant, Great Portland-street, W., and Mr. Lang will be entertained by his former house surgeons, clinical assistants, and colleagues on the honorary staff, to whom a circular has been sent. At the same time any old Middlesex student who would like to be present and to do honour to Mr. Lang on this occasion will be heartily welcome, and is requested to communicate with Mr. Arnold Lawson, 12, Harley-street, London, W., who will be pleased to answer any inquiries.

Annotations.

"Ne quid nimis."

RECENT PLAGUE IN CUBA.

SCARCELY two years ago a small localised outbreak of plague occurred at Havana, the capital and chief seaport of the island of Cuba, and although at the time an excessive mortality among rats was observed none of the animals that were bacteriologically examined yielded satisfactory evidence that they had died from plague. As a result of the very vigorous enforcement of anti-plague measures under the direction of Dr. Juan Guiteras, chief of the Cuban Health Department, the disease seemed to subside as suddenly as it had appeared. It was, however, never made quite clear from what source the plague infection had been derived. Simultaneously with the Cuban outbreak in 1912, a larger and more virulent epidemic occurred in the island of Porto Rico, which, like Cuba, is under the protection of the United States; here there was an undoubted epizootic of plague among rats. In this instance also the origin of the first cases was never cleared up. Nothing was heard of plague in rats or man at Havana from midsummer, 1912, until the beginning of March of the present year, when up to the end of April 12 cases came under observation, along with a few other suspected instances. Though this number is small, there are some circumstances which suggest the possibility that the situation might become more serious than is at first sight apparent. Unofficial statements have recently been published in the press to the effect that the disease is spreading in Havana, but no details are brought forward in support of the allegation. The disease has now appeared at Artemesia, a town 35 miles from Havana. So far as we can learn none of the reports have indicated the precise origin of this second outbreak, nor has any mention been made whether the local rats are or are not involved. Dr. Guiteras, however, is reported as having said that plague was brought to Cuba, not by rats, but by fleas conveyed in sacks of sugar, but it is quite possible that early this year a fresh importation of the plague infection from some affected port took place. In this connexion it may be pointed out that this year, up to the time of writing, there has been no reported occurrence of plague in any other of the West Indian islands. Last summer there were rumours in circulation that cases had been recognised in Haiti, but this was officially denied, with what truth it is not possible to say, as affairs in this negro republic are conducted in a different way from that of other governments. At the present moment plague is prevalent in some parts of Brazil, in the port of Bahia for example, and cases have recently occurred in Venezuela, at Caracas. At the end of 1913 the disease was present in some River Plate ports, as well as in some of the inland districts of the Argentine. Although the ports on the west coast of South America are situated at a considerable distance by sea from the West Indies, it would not be impossible for rats from one or other of the ports now suffering from epidemic plague in Chili, Peru, or Ecuador to be conveyed on shipboard and landed at Havana or any other West Indian port, either concealed in crates and packages or in some other way, unless very special precautions had previously been taken. If, however, the recent plague cases in Cuba were not due to a fresh importation of the disease but to a recrudescence in virulence of the 1912 infection, which has perhaps been maintaining itself in a mild form out of sight among the local rats, the situation would have to be regarded in a more serious light. It would obviously be difficult to get rid at once of an already established infection of which the precise extent and distribution are not known, and which would require much time and trouble to eradicate. Meanwhile there would be a danger of the disease being exported to some other ports in the Gulf of Mexico or along the Atlantic seaboard, from which the infection might perhaps spread up the great rivers into the populous districts in the interior of the United States. There was a time when such a prospect would have created consternation in the public mind; but nowadays confidence in the responsible authorities has gradually increased, and they are left to deal suitably with the emergency. So long as there is no concealment of the facts, and so long as the public officials concerned in the matter are kept informed of all the foci of the infection, plague can be effectually controlled by the application of those measures which are the outcome of the recent advances in our knowledge of the malady and its modes of spreading. As to Havana, Dr. Guiteras and his staff may be relied upon to take every needful step for suppressing the present outbreak and for preventing its extension to other places. There is, however, the possibility that before the existence of plague in Cuba was recognised this year some exportation of the infection may have taken place. This will probably entail upon those ports trading with Cuba a certain amount of increased care and vigilance with a view to searching out and dealing with the first evidences of plague discovered in rats or man, so that the disease may be promptly controlled and the infection destroyed.

THE SUPPLY OF COD-LIVER OIL.

WERE the question to be raised which is the most important fish from the medical point of view, the cod, no doubt, would take the first place. The unwavering popularity of cod-liver oil in diseases of nutrition is all the more remarkable in this age of substitutes, which, in spite of vigorous pushing, have failed to oust the remedy of our childhood. A more insidious danger to the good name of cod-liver oil has been the sale of oil taken from the liver of the shark and other fish as cod-liver oil. To what extent this practice has been followed in the past it is, of course, impossible to say, but it may safely be assumed that the cod-liver oil as sold to-day by the leading wholesale chemists is exactly what it calls itself. The demand for the genuine article being great, the consumer is naturally interested in the source of his supplies, particularly with reference to the adjustment of supply to demand. Much of the cod-liver oil on the market comes from the Lofoten fisheries on the west coast of Norway, where at certain seasons of the year the cod is caught in millions. The fish are said to be so crowded together that the weighted line may fail to reach the bottom, being intercepted by the intervening wall of fish. This statement, which savours suspiciously of fishing tales in general, suggests a boundless supply, and so it may be. But e Norwegian Government has not rested satisfied with such a vague estimate of one of its most important sources of wealth, and it has instituted a systematic research into the life-history of the cod. The Director of Fisheries, Dr. Johan Hjort, has lately given an account of these researches which have thrown considerable light on the migrations of the cod and on its rate of growth. In 1913, 2400 cod were caught, marked, and put back. Of these, 279 were caught again in the same season, a result which shows that the drain on the supply must be heavy. A cod which was marked on March 17th, 1913, at Henningsvaer was caught again on Feb. 12th, 1914, at Sörvaag. This shows that the cod returns to the Lofoten banks year by year, and, incidentally, that the method of marking adopted stands the test of time. The rate of growth of the cod is shown by the increase in length from 8·7 to 19·5 cm. observed in the case of a cod caught on May 26th, 1913, and again on Feb. 19th, 1914. It was also found that cod had travelled as many as 1700 kilometres during the few months which had elapsed between the marking and the second catch. Though the proportion of cod caught a second time is surprisingly great, its rapid growth and its wide range of excursion are reassuring features to the fisherman and the physician.

PARTIAL CONTINUED EPILEPSY.

THE above name has been given by Kojewnikow to a curious condition in which there may occur clonic spasms of certain groups of muscles similar in many ways to those of Jacksonian epilepsy, but which differ from them in that the spasmodic movements are maintained over long periods of time. In this latter feature it resembles myoclonus. Kojewnikow and Bruns in 1894 were the first to direct attention to the condition. Probably similar cases have been previously observed, but there is little doubt that they have been erroneously classed as myoclonus. The distinction, however, is afforded by the epileptic character of the onset of the spasmodic movements. A case of partial continued epilepsy has been carefully recorded recently[1] in a man, aged 34, the sufferer from paraplegia secondary to Pott's disease. Apart from this lesion, however, he began to suffer from clonic spasms of the right arm; later they involved the hand, and then the leg of the same side. Some days after there developed a flaccid paralysis of the right arm; no contractures followed. Then there occurred an epileptic crisis limited to the right arm, but which, instead of lapsing, has persisted in the form of clonic movements ever since, with occasional lapses. The Jacksonian crises in this case differ from the classic radiating form in several ways. The muscle groups concerned are variable at different times; now it is hand and face, without the arm; at other times it may be hand and right hypochondrium. The length of the crises is variable. Bromides can lessen the spasms for several hours. The form of the spasms may undergo abrupt changes: they may be rapid and of small amplitude and within a moment of time give place to slower and larger oscillations; sometimes a short pause intervenes. The interpretation of such a case is difficult. It is hard to understand why the lesion, which in this case is stated to be of tuberculous character and situated at the junction of the middle and inferior portions of the ascending frontal convolution, near the hand centre, should cause permanent clonus and not intermittent epileptiform crises. Clinically, it may be of importance to recognise these cases, as surgical intervention could be considered—a proceeding which would hardly be suggested for myoclonus.

THE USES OF EMETINE.

PERHAPS the most important therapeutic advance of recent years is the treatment of amœbic dysentery and hepatitis by hypodermic injection of emetine. We are indebted for it to Professor Leonard Rogers, of Calcutta.[1] He found that amœbæ were rendered inactive and apparently killed by a solution of emetine as weak as 1 in 100.000. The experience of many observers all over the world have shown the great value of this treatment which produces a veritable *sterilisatio magna*, although curiously the phrase has not been used here, but has been applied prematurely to a still more widely known new remedy. Some recent observations, principally French, show that emetine is useful in other diseases than dysentery. In a communication to the Académie de Médecine of Paris on April 14th M. L. E. Bertrand referred to the fact that Dr. Allen Hutchison, a medical missionary in China, had used emetine with most satisfactory results on patients infected with schistosomum japonicum and passing glairy and sanguineous stools. M. Tribondeau has treated three cases of dysentery in which the stools contained spirilla (without amœbæ). In two or three days the stools became normal and the spirilla disappeared. He also found the treatment beneficial in mucous colitis. Hæmoptysis and gastro-intestinal hæmorrhages are now treated in the French hospitals by emetine. Several communications on the uses of emetine have been made at the Société Médicale des Hôpitaux of Paris. At a meeting on Jan. 23rd, M. Louis Rénon referred to excellent results which had been obtained in hæmoptysis. He mentioned two cases of cancer of the lung under his own care in which the hæmoptysis disappeared under injections of emetine. He also referred to cases of intestinal hæmorrhage due to cancer of the lower part of the large intestine and to membranous colitis in which good results were obtained from subcutaneous injections of 4 centigrammes of emetine. M. Rénon himself had obtained rapid results in five cases of severe gastro-intestinal hæmorrhage—hæmatemesis and melæna. In two cases the hæmorrhage was due to hepatic cirrhosis. In one a woman had the gall-bladder removed for cholecystitis in November, 1912, too late to prevent gradual infection of the biliary passages and hypertrophic cirrhosis of the liver. While undergoing treatment at Carlsbad severe intestinal hæmorrhage occurred and did not yield to ordinary treatment. Duodenal ulcer was suspected and laparotomy was proposed. M. Rénon was summoned and thought that ruptured intestinal varices were a more probable cause than ulcer of the duodenum. He advised that operation should be postponed and emetine administered. The drug was not given and the patient's condition became desperate. When M. Rénon saw her again four days later she was pale as death and the pulse was uncountable. Under calcium chloride and the application of cold to the abdomen the hæmorrhage had diminished, but on the following day it became more abundant. He injected 6 centigrammes of emetine and 10 cubic centimetres of hæmostyl. The effect was most remarkable; the hæmorrhage permanently ceased and recovery ensued. In the three other cases of intestinal hæmorrhage, due respectively to tuberculous ulceration, uræmic ulceration, and ulcerative enterocolitis, emetine was used alone with equally good result. M. Rénon has obtained striking results from injections of 2 centigrammes of emetine once, twice, or thrice daily in desperate cases of bronchopneumonia in the aged. At the following meeting of the society M. O. Josué and M. F. Belloir reported excellent results from the treatment in intestinal hæmorrhage in typhoid and paratyphoid fever and alcoholic hepatitis. At the meeting of the society on March 13th M. Félix Ramond and M. Jacques Durand reported good results in acute and chronic bronchitis in consequence of the more fluid character of the expectoration after injection of emetine in daily doses of 4 to 8 centigrammes.

A STUDY OF TUBERCULOSIS CONTACTS.

THE May number of *Public Health* contains reports on syphilis and public health, by Dr. F. W. Mott, and studies in the epidemiology of pulmonary tuberculosis, by Dr. A. S. M. Macgregor, both of which are well worth attention from those concerned in practical hygiene. An editorial note draws attention to the contrast between syphilis and tuberculosis in the nature of the administrative measures needed to reduce the prevalence of the diseases; it is pointed out that in syphilis we are concerned mainly with the seed, whereas in the case of tuberculous disease we are increasingly learning how large a factor the soil is in determining the incidence of attack. With the knowledge gained in the last few years there is prospect of doing much by well-designed administration to reduce the mischief caused by syphilis; in the case of tuberculosis, where an elaborate machinery for dealing with individual cases has already come into being, the conditions to be combated are much more complex and the underlying principles of action are less easy of definition. These observations have special relation to the studies made by Dr. Macgregor on the incidence of phthisis on the population of Glasgow judged by notifications, deaths, and the social condition of the cases as evidenced by the number of rooms in the tenements which they occupy. Dr. Macgregor has given the results of following cases notified in 1910 into the present year. Among other interesting figures are those which suggest that in the case of Glasgow children of school age stated to suffer from pulmonary tuberculosis a fatal result, if it occurs, nearly always happens within two years, and that the survival of a phthisical child for two or three years after recognition of its disease establishes a strong probability of its eventual arrest. The facts as to contacts in the houses affected are also noteworthy. The incidence of tuberculosis was distinctly more marked among the contact population than in the general population, particularly in the one-roomed tenements, but there was less gradation than might have been expected in the incidence on the contact populations living in two, three, and four rooms respectively, and the figures once more raise the disputed question as to the real meaning of the occurrence of tuberculosis in the contact. It would be natural to assume, as is now customary in daily practical work elsewhere among such cases, that the excess of tuberculosis among the contacts resulted from their exposure to the known infection, but it still appears possible to explain a large part of the excess on the assumption that Dr. Macgregor was dealing with susceptible families, and that the contacts might not have fared better if the primary case in each family had not existed. The excessive incidence of tuberculosis on the occupants of the one-roomed tenements, again, may be due mainly to contact infection or may be explained by the hypothesis that there are more susceptible people among the poor than among those better off, and that under stress of poverty resulting from long illness in the family there is a special tendency for the tuberculous family to resort to the one-roomed tenement. These questions are of much importance, and it would seem that the only means by which they can be satisfactorily solved is by exact local inquiries into all the circumstances of notified tuberculosis cases, these being taken in sufficient numbers and over a long period of years. It may be hoped that investigations on the lines of those of Dr. Macgregor in Glasgow will be undertaken before long for other areas, and that local authorities, in their desire for "results," will not grudge the time needed for the continuance of such work. The importance of obtaining exact accounts, not only of possible exposure to infection, but also of conditions of environment and the racial and family characteristics of the cases in respect of tuberculosis, should be kept in mind by tuberculosis medical officers and others who are now securing records of the circumstances of tuberculosis cases and their home contacts at different periods.

MEDICAL SOCIETY OF LONDON.

THE concluding meeting of the session was held in the rooms of the society on Monday, May 18th, Sir David Ferrier, the President, in the chair. The annual oration was delivered by Mr. Robert Jones on the Surgical Aspect of Poliomyelitis, and will be published in full in our next issue. A vote of thanks to the orator was proposed by Mr. C. A. Ballance, seconded by Mr. A. H. Tubby, and carried by acclamation. The Fothergillian medal was presented to Professor J. G. Adami, F.R.S., of Montreal, by the President, who briefly related the history of the medal and paid a warm tribute to the services which Professor Adami had rendered to medicine in the domain of pathology. Professor Adami, in reply, thanked the President and Fellows for the great honour they had done him, and through him the profession of the Dominion to which he belonged. Afterwards the customary annual conversazione was held. A very large number of Fellows and guests attended.

SPINAL SCIATICA.

AN important discovery was made in the pathology of sciatica when it was found by Dejerine and his co-workers that the modifications of sensibility in this condition occurred in most cases in regions corresponding to the segments of the spinal cord and not to the peripheral nerves. This neurologist believes that in such cases we are dealing with a process of intradural distribution, which gives rise to a patchy meningitis, and which is associated with a more or less marked lymphocytosis in the cerebro-spinal fluid. The absence of definite motor symptoms, he explains, is probably due to the posterior situation of the local meningitis. Syphilis is believed to be the commonest cause. In the *Revue Neurologique* (1913, Vol. XVII., p. 253) J. M. Raïmiste reports four cases of this spinal sciatica. All the cases presented the so-called classical symptoms of sciatica, but in addition there was exaggeration of the reflexes on the two sides. The sensory signs were variable, but there was some disturbance in all. In Case 1 there were hyperæsthesia, hypalgesia, and depression of temperature sense over definite regions in the limb; in Case 2, hyperæsthesia and hyperalgesia to pain and temperature; in Case 3, hyperæsthesia, hypalgesia, and lessened temperature sense; and in Case 4, depression of all forms of sensibility. On the motor side there was usually a slight degree of weakening. Of special interest in these cases was the result of lumbar puncture. In all there was within a few hours marked relief from the pain, and further, in three cases the recovery appeared to be lasting and complete.

RELAPSES IN ACUTE ARTICULAR RHEUMATISM.

ONE of the most characteristic and troublesome features of acute articular rheumatism is its tendency to relapse, uncontrolled by salicylate. One attack predisposes to another, with results that are most serious for the patient. It is generally agreed at the present time that acute rheumatism is an infectious disease caused by a living organism, and that it should be classed among the acute specific fevers. Relapse in these means re-infection, and in the case of acute rheumatism it is very commonly believed that the infecting agent "lies perdu" in the tonsils or naso-pharynx between the relapses, gaining access to the blood and giving rise to new arthritic manifestations as often as a relapse occurs. Good reasons have been given for believing that the throat is a common channel for infection here, but it is hardly likely that it is the only one. Professor J. M. Beattie has brought forward[1] experimental evidence to show that in rabbits, at any rate—animals in which the virus of acute rheumatism readily produces an arthritis with a tendency to relapse—the infecting organism can be recovered and cultivated from the synovial membranes of the larger joints in the intervals between the relapses. Even when no relapse occurred the organism—a streptococcus—could be recovered from the joints in many instances, in one as much as 12 months after the original infection had taken place. It is clear, therefore, that the virus of acute rheumatism may lie latent in the articular synovial membranes of the rabbit for long periods of time. Is the case the same with human beings? The question is answered in the affirmative by Professor Beattie and Dr. A. G. Yates. These authors endeavoured to obtain bacterial cultures from the synovial membranes of the knee-joints in 89 cases from the post-mortem room. Sixty were sterile, 12 contained putrefactive organisms or staphylococci. and 17 contained streptococci or diplococci. In 10 of the 17 cases the organism isolated was of the streptococcal type found in acute rheumatism, and 9 of the 10 were from cases with a definite rheumatic history or post-mortem evidence of rheumatism. Nine of these 10 organisms were inoculated into rabbits, and 6 of them produced the characteristic recoverable arthritis. while only one clearly failed to do so. It is pointed out that of the 79 cases that did not yield the streptococcus, only 4 could be regarded as possibly rheumatic. Professor Beattie concludes that the relapses of rheumatism are due to the persistence of the causal organism in the tissues of the joints. He suggests that treatment should be carried on in the apyrexial periods between the relapses in order to destroy the virus. Salicylates have often proved ineffective here, and the search for some more potent drug should be made. In addition, he suggests treatment with vaccines during the latent periods of the rheumatic infection. He is very sceptical of the value of vaccines in acute processes, but believes that for microbic conditions which are not particularly active their value is beyond question.

COMPLEMENT FIXATION IN TUBERCULOSIS.

FEW better examples can be found of abstruse and seemingly trivial scientific observations which have ultimately proved to be of the greatest practical importance than the fixation or deviation of complement in the presence of an immune serum and the appropriate antigen. At the present time not only has the Wassermann reaction for syphilis become a matter of daily investigation, but in other diseases the same principle is being applied as a diagnostic procedure with conspicuous success. Such is the case in the diagnosis of glanders in horses, and in the sphere of human tuberculosis there are indications that a valuable test may be ultimately afforded when the phenomena have been adequately elucidated. Further investigations, in continuation of those already published in our own columns, have been made by Mr. Leonard Dudgeon, Dr. W. O. Meek, and Dr. H. B. Weir[1] which are of importance in this connexion. Some difficulty has hitherto existed in preparing a satisfactory antigen for this test, experiments having been made with various tuberculins and bacterial cultures. Dudgeon finds that an alcoholic extract of the bacilli is the most useful and trustworthy preparation. It is a matter for regret, however, that no details of the actual manufacture of the antigen are given. In human patients with tuberculosis of the lungs a positive reaction was obtained in 89·3 per cent., and this figure might have been increased if further examinations had been made in certain cases in which only one test was carried out. The serum often gave a positive reaction in dilutions of 1 : 100 or even 1 : 1000. The strength of the reaction and even its presence and absence may vary in the same patient from time to time in a curious manner which is not at present explicable. Thus no relationship could be traced between the condition or stage of the disease and the amount of immune body present in the serum, but on the whole the severe cases showed the presence of more immune body. The intercurrence of a febrile exacerbation similarly had no constant effect, the reaction appearing or disappearing, or becoming stronger or weaker, without any obvious reason. No prognostic significance could thus be attributed to the phenomenon, variations in both directions occurring irregularly in patients who were improving and in those going downhill. The actual diagnostic value of the test is not yet established, but it bids fair to form at least a useful supplement to the search for bacilli in the sputum in pulmonary cases. In surgical tuberculosis the percentage of positive reactions does not appear to be so high, and here a negative result would seem to be of little importance. In any case a single failure to react must not be taken to exclude tuberculosis, while frequent negative findings may at times occur in infected persons. A positive result appears to point with fair certainty to tuberculous infection, but no definite inference can be drawn as to its activity or quiescence. This week we publish the results of a further research on the Complement Fixation Test for Tuberculous Disease, by Dr. A. C. Inman, the superintendent of the Brompton Hospital Laboratories. He gives details of the manufacture of the antigen, and also supplies references to Professor Besredka's publications. The technique of the test is then fully explained. Dr. Inman gives an interesting account of his investigations and the conclusions at which he has arrived. The methods of previous observers left much to be desired, and the test proved so fallacious that little value could be attached to it. With improvement in technique, however, the reliability of the test has made a marked advance.

X RAYS IN THE DIAGNOSIS OF GALL-STONES.

UP to the past year the demonstration of gall-stones by the X rays has been regarded as so unusual as to constitute a curiosity. American workers have now so improved the technique that this method of examination has become important. In the *Boston Medical and Surgical Journal* of April 30th Dr. A. W. George and Dr. L. Gerber have described the present position of the problem. They began to find the shadows of gall-stones by accident during the course of bismuth examinations of the alimentary tract. Gradually the accidental findings became so frequent that they found it advisable to look for gall-stones in every case. They have now adopted the routine of examining the gall-bladder in every patient before giving the bismuth meal. Pure cholesterin stones do not interrupt the X rays to any appreciable degree, so that shadows of them cannot be distinguished. Fortunately such stones are not common, or at least do not cause many chronic disturbances. When the gall-bladder is chronically inflamed by repeated infection the stones deposited have the characteristic lamellæ of calcium and bile salts encrusted on the cholesterin core. It is only the calcium ingredient that is shown by the X rays, and the clearness of the demonstration on the plate depends on the amount of calcium present. As a rule in nearly every case of symptoms referable to gall-stones there is some calcium. Dr. George and Dr. Gerber think that it will soon be possible to state whether gall-stones containing calcium are present or not. Their technique for demonstrating gall-stones is very simple. The patient lies upon the table with his face down. The plate is placed under the right hypochondriac region. The maximum of definition is obtained with a very small diaphragm, 1½ inches in diameter, and a very small cylinder placed close to the back. It is preferable to use a fairly soft tube with a rapid exposure. It is better not to use intensifying screens, but the simple plates as in kidney work. The gall-stone shadows will vary according to their calcium content. Often there will be a central light area with a peripheral calcium shadow. Occasionally irregular deposits of calcium corresponding to the lamellated structure may be made out. As a rule the faceted outlines are clear, but a shadow suggesting a single mass may be due to closely packed gall-stones.

---

[1] THE LANCET, Jan. 4th, 1913; Journal of Hygiene, April 27th, 1914.

Evidences of gall-bladder disease are usually shown at the subsequent bismuth examination in the form of signs of pericholecystitis. The commonest sources of error in the diagnosis of gall-stones are renal calculi, calcified mesenteric glands, and costo-chondral ossification. Gall-stones may be distinguished from renal calculi by taking plates with the patient lying first on his abdomen and then on his back. Gall-stones are nearer to the anterior abdominal wall; therefore the anterior plate will show the shadows small and sharp, whereas the posterior will show them large and blurred. The reverse holds in renal calculi. Calcified mesenteric glands will be found to occupy different positions in different plates on manipulating the abdomen between the exposures. A calcified costal cartilage will be continuous with a rib.

A GENERAL HOSPITAL AND A MUNICIPAL TUBERCULOSIS SCHEME.

THE rapidly growing perception on the part of Government departments and local authorities of the importance of tuberculosis problems is leading to displays of commendable energy, even if some of the measures set on foot have not been thought out as carefully and organised as intelligently as they might have been. Still, experience teaches, and those in charge of all varieties of local anti-tuberculous efforts may learn a great deal from the first report, just issued, of the municipal dispensaries scheme inaugurated last year by the borough of Lambeth in conjunction with St. Thomas's Hospital. It is not every borough in London which has a big general hospital within its borders; but a good many of them have, and their medical officers of health may well take note of the advantages which accrue from the coördination of the voluntary hospital expert and his hospital facilities with the tuberculosis medical officer. Hitherto the voluntary hospitals have, to all intents exclusively, treated disease as it affects the individual and not as it affects the community. In the control of tuberculosis there is especial need of concerted action between the curative and the preventive agencies; and in Lambeth this ideal is being ensued by the dispensaries scheme there adopted, which was the first endeavour to utilise a general hospital in conjunction with municipal organisation. As far as London is concerned, this scheme was the first to obtain approval from the Local Government Board and the Insurance Commissioners, and it has formed the basis upon which several such schemes have been developed in other districts. There are two municipal dispensaries in Lambeth, one of which is housed in a special part of the out-patient department at St. Thomas's Hospital. They are worked on the same lines, and each is managed by a tuberculosis medical officer, working under the medical officer of health. The patients are interchangeable between the two, and the resources of each are open to the patients of the other. This is of special value to the Effra-road dispensary, for in difficult cases the medical officer can obtain at St. Thomas's Hospital the benefit of all their modern appliances and special departments—pathological, chemical, laryngological, radiological. Moreover, the tuberculosis officer in charge of the St. Thomas's dispensary can requisition the services of members of the visiting medical staff of that institution, and has also at his disposal a special ward of ten beds for purposes of observation and tment. The working of this valuable scheme, as disclosed in the report now issued, thoroughly justifies the forethought expended upon it, and the report is a most useful contribution to the literature of the concerted attack on tuberculosis which the national conscience is beginning to demand.

DIAPHRAGMATIC PLEURISY SIMULATING GASTRIC ULCER.

TWO interesting papers have been recently published[1] drawing attention to the intimate resemblance in the symptoms due to inflammatory conditions of the diaphragmatic pleura and those of gastric or some abdominal conditions. The pain distribution in diaphragmatic pleurisy was shown by De Mussy in 1879 to be referred to two points—one over the phrenic nerve in the neck and the other in the hypochondrium. In 1911 Capps reported his ingenious observations upon what occurred when the diaphragm was irritated by means of a blunt wire introduced into the needle before fluid from the pleura was removed. He found that pain was elicited. If pressure was made upon the outer edge of the diaphragm there was pain in the abdomen; if made upon the central portion pain was referred along the ridge of the trapezius. There was often associated hyperalgesia of the skin. Dr. Dexter reports two cases, in both of which the urgent symptoms were abdominal. In one case there was pain in the left side of the abdomen; in the other it was in the right. In one case there was vomiting. In both, in addition to the abdominal pain, there was tenderness over the trapezius corresponding to the side in which the abdominal pain was felt. Hiccough was also present. In both cases there were found physical signs, slight in character, at the basal region of the lung. Still more striking were the eight cases of Dr. Mace. In all these cases the symptom-complex is stated to be due to adhesions between the diaphragm and basal pleura, and is caused not by acute inflammation, but rather by mechanical adhesions of tuberculous origin. The pain may thus arise whilst the patient feels quite well. There may be no lung symptoms, and the symptoms in the distribution of the pain simulate gastric ulcer. Thus, the pain may be worse after food; it goes through to the back and a tender spot can be found to the right of the lower dorsal vertebræ. "Wind" may be a very troublesome symptom. Hæmorrhage may even occur. Radiograms accompany the records of these cases, and in all there is definite evidence of diaphragmatic adhesions; there is also evidence of tuberculous infection of the lungs. In two cases operations had been performed for the relief of stomach symptoms, but without effect. In most of the cases the patients had undergone rigid dietetic treatment and were much emaciated. Following the radiographic records in these cases, which revealed the cause, treatment was directed primarily to the lung condition; tuberculin was given and liberal diet instituted, with satisfactory results in many instances.

THE President of the Board of Trade has appointed a committee of seven, with Sir William Collins, M.D., as its chairman, to inquire into the working of the Railway Employment (Prevention of Accidents) Act, 1900.

NITON AS A THERAPEUTIC AGENT.

By SIR WILLIAM RAMSAY, K.C.B., F.R.S.

THE application of niton ("radium emanation") as a therapeutic agent was tried in my laboratory at University College in 1904. A number of small bulbs, each containing a solution of radium bromide, were sealed to a Töpler pump; the water of the solution yields a mixture of oxygen and hydrogen gases, carrying with it the niton. That mixture was collected at convenient intervals, introduced into a small explosion burette, and by means of a spark the oxygen and hydrogen were made to unite. There is always an excess of hydrogen (due to the formation of hydrogen peroxide in the solution), and this hydrogen carries with it the niton. By introducing approximately half its volume of oxygen and again passing a spark the hydrogen is made nearly to disappear, and the niton remains in the explosion burette. The remaining trace of gas can be expelled into a small tube containing water, and the burette washed out with a trace of water. In this way a solution of the niton is obtained, and in the earlier experiments it was injected into the patient. The results have been summarised by Sir Lauder Brunton in the *British Medical Journal* of Jan 25th, 1913 (see also THE LANCET, Feb. 12th, 1910).

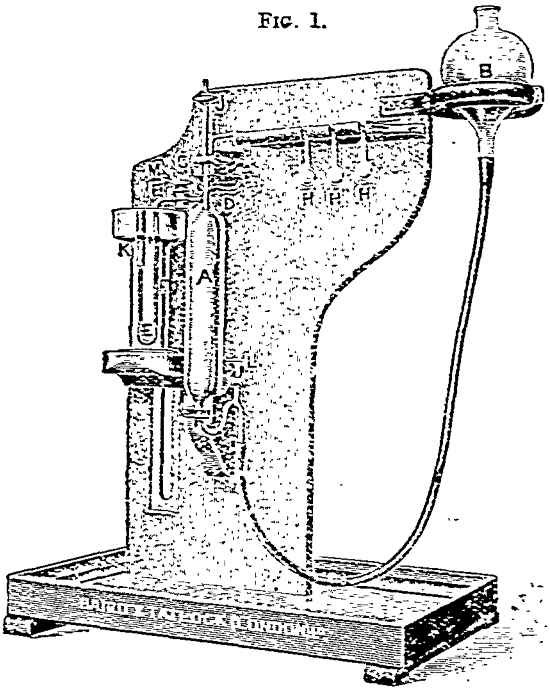
Since the use of radium has increased I have always recommended its application in the form of niton rather than as a salt of radium. The original method, as everyone knows, was to spread the radium salt on a plate or to enclose it in a thin glass tube; in the former case, it was protected by a layer of varnish; in the latter, the glass tube was enclosed in one of platinum or silver. Apart from the risk of loss of the precious radium, this plan has the disadvantage that the radium is not continuously in use; it is seldom applied during the night. But the production of niton from radium is continuous; it goes on night and day. And the radiating power of niton is 75 per cent. of that of the radium from which it is derived. It is true that the niton decays; but it can be used at any moment when its "strength" is known accurately; and a curve can be sent to the user, which will enable him to know exactly what he is doing when he applies the active material. For this purpose the niton must be introduced into appropriate forms of apparatus—tubes, bulbs, and hollow flat discs. These may conveniently be made of iron or of nickel; neither iron nor nickel is attacked by mercury, and nickel is preferable to iron, inasmuch as it is not liable to rust.

Description of Apparatus.

It has occurred to me that it might be useful were I to describe a simple form of apparatus by means of which niton can be enclosed in appropriate vessels. This apparatus does not include a pump; its manipulation is so simple that any workman can be entrusted with it after a few lessons. I have had a small form of such an apparatus in use for more than a year, and it functions admirably. I will describe it, however, as if it were to dispose of the niton generated by 500 mgm. of radium bromide; should less be in use, the size can be modified according to scale. It may be stated that the yield of mixed oxygen and hydrogen gases from 500 mgm. of radium bromide, amounts to approximately 25 c.c. in a week.

Fig. 1 gives a sketch of the apparatus. A is a reservoir of about 500 c.c. capacity; it is connected with a mercury reservoir, B, by flexible thick-walled rubber tubing. C is a trap, to make sure that no air enters A. At D platinum wires are sealed through the narrow neck of A. E is an inverted siphon, issuing in a mercury trough F. G is a two-way stopcock, connecting on the one hand with the radium bulbs H (it is advisable to have the tube of narrow bore); the bulbs may be more numerous, and may be kept in a *locked cupboard or safe*, through a hole in the side of which the connecting tube passes. I is a piece of thick-walled rubber tubing; J is a hollow plate to be fitted, or it may be a silver or nickel tube, or, indeed, any form of hollow applicator which it is required to fill with niton; and K is a test-tube containing pure oxygen.

FIG. 1.



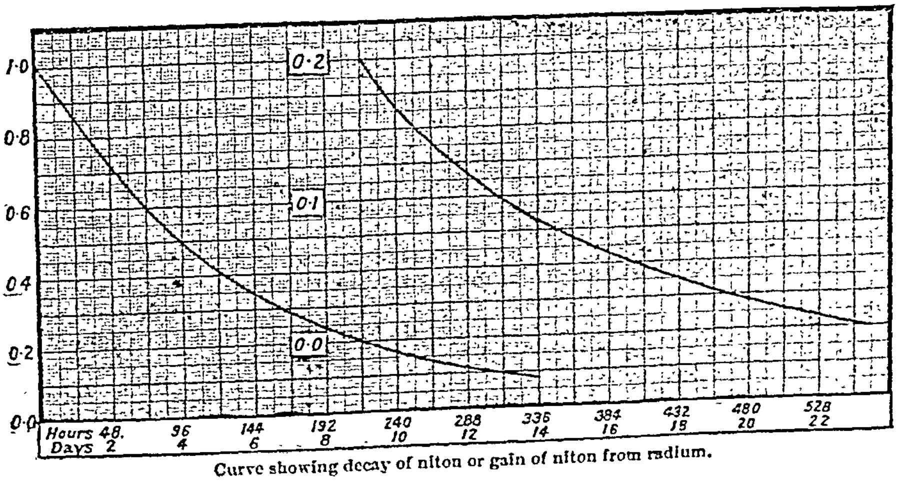
How the Apparatus is Employed.

This apparatus is used in the following manner. 1. In starting the whole work the radium bulbs must be cleared of air. The reservoir B is raised, and the stopcock M is opened and all air is expelled out of A, through the inverted syphon, the oxygen tube being removed temporarily. 2. The reservoir B is then lowered, M being closed, until the level of the mercury in A has sunk to L; A is now vacuous. 3. The stopcock G is now opened, so as to communicate with H; the air in H enters A; G is closed, and M is opened. On raising B this air is expelled through the inverted syphon. This operation is repeated four or five times; the radium bulbs are now practically free from air.

It is necessary here to put a supposititious case. If 500 mgm. of radium are in connexion with the pump, and it is required to fill a hollow plate with the equivalent of 500 mgm. of radium, then, referring to the drawing, B is lowered, so as to evacuate A, and the tap G is turned, so as to bring A in communication with J. The air in J enters A. G is closed, M is opened, and this air is expelled through the inverted syphon. B is again lowered, M being closed, and the mixed oxygen and hydrogen gases which have accumulated for 24 hours in the radium bulbs are drawn into A. As the total gas evolved from 500 mgm. of radium is about 25 c.c. in a week, there will be the seventh part in 24 hours, or 3·6 c.c. The space in the radium bulbs may be taken as negligible compared with the 500 c.c. capacity of A; if it amounts to 10 c.c. it will be a fiftieth part of the whole. B is then raised, and a spark is passed through the sealed-in wires at D; as a rule, about half a cubic centimetre of hydrogen will remain after explosion has taken place. By turning the stopcock G to communicate with J, that gas will enter J. Care must be taken that no mercury reaches I; that can be seen in the glass tube below I. If B is somewhat lowered, and gradually raised, the gas can be allowed to enter J slowly, and it is easy to stop when the mercury has risen to just below the rubber tube I. A convenient plan is to have the vertical tube from J of thin lead, such as is used for vaccine tubes, and to seal it by pinching with a pair of pliers. In order not to waste the small amount of gas remaining above the stopcock G, a vacuum may be again made in A by lowering B, and on closing the stopcock G almost all that "waste" gas is drawn back into A, ready for another operation.

The 3·6 c.c. being the amount in equilibrium with 500 mgm. of radium bromide after 24 hours, it will contain 0·15 of the total amount of niton in equilibrium with that quantity of radium bromide (see curve, Fig. 2); and assuming the "efficiency" of the niton to be 75 per cent. of that of the radium, it would be equal in "emanating power" to 0·11 × 500, or 55 mgm. of radium. The applicator, therefore, may be taken as practically equivalent to a plate covered with 50 mgm. of radium if used at once. If kept for 24 hours it would be equivalent to 0·85 of that "strength" or to 42·5 mgm.; if kept for 48 hours to 0·7 of that strength or to 35 mgm., and so on. The curve gives at any moment its "strength." If much more than 3 c.c. of gas have to be exploded it is advisable to lower the pressure somewhat by depressing the reservoir B before passing the spark. To produce a spark a cheap little coil, costing only a few shillings, suffices; a couple of dry cells will operate it.

FIG. 2.



Curve showing decay of niton or gain of niton from radium.

Tube-shaped Applicators.

The fitting of a tube-shaped applicator is carried in the same way. If the tube is required to be a very fine one, however, the amount of gas may be too large. I find a good plan to be the following. It is possible by lowering the reservoir B and opening the stopcock M very carefully to draw mercury, drop by drop, into A. By depressing the test tube K over the inverted syphon an amount of oxygen, equivalent to one, two, or more drops of mercury can be drawn into the inverted syphon; supposing two drops of mercury have fallen, then their volume of oxygen will remain in the inverted syphon. The oxygen tube is then raised and mercury allowed to enter by opening the tap M until the oxygen passes into A. With a little practice it is not difficult to introduce a small quantity of oxygen, half the volume of the hydrogen remaining after the first explosion. A second explosion is made, and the hydrogen nearly disappears; the niton is mixed with this very small residue. Instead of having a lead tube connected with the applicator, in this case a piece of glass quill-tubing, which has been drawn out to a wide capillary and closed at the end, as in Fig. 3, is slipped into the rubber tube at I. This tube before beginning the operation is emptied of air, as already described for the disc-shaped applicator. Then the niton is exploded and the residue again exploded with a trace of oxygen, as already described; and the infinitesimal residue is forced up into the capillary tube by raising the reservoir B, followed by mercury. By means of a fine mouth blowpipe flame the capillary tube can be fused at the constriction; and the niton now enclosed in the capillary can be introduced into a metal tube of the desired thickness.

FIG. 3.

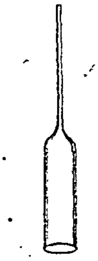


FIG. 4.

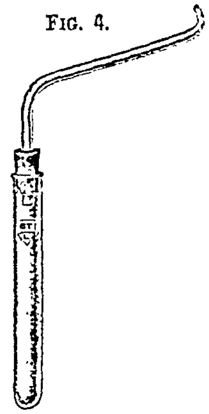


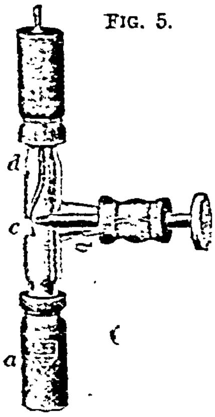
Filling the Oxygen Tube.

To fill the tube K with oxygen is very simple. A piece of tubing about 6 inches long and ¼ inch wide is closed at one end. Into it is placed some solid potassium permanganate so as to fill it to a depth of 2 inches. The upper part of the tube is then drawn off and bent as shown in Fig. 4. On warming the permanganate with a Bunsen burner a steady stream of oxygen comes off, which is allowed at first to bubble through the mercury in the trough F. After a fair quantity of oxygen has passed it can be taken for granted that the air in the permanganate tube has been displaced by oxygen. The bent end is then passed under the open end of the inverted test-tube, which is filled with oxygen. Such a permanganate tube will serve many times, for it stops giving oxygen as soon as it cools.

Recovery of Residual Niton.

After a tube has been used for applications it still contains niton, and it is desirable not to waste it. The amount can be calculated accurately from the quantity of radium bromide from which it has come, and its age; or it can be read off from the curve. Hence it may be re-used, mixed with more from the source—the radium bromide. To effect this a small glass apparatus, shown in Fig. 5, may be employed; *a* is the piece of rubber tube shown at I (Fig. 1); *b* is a piece of steel with a sharp-cutting edge at *c*; *d* is the lead tube of J, closed by nipping. This lead tube is pushed down so as to pass the edge of the stopcock *b*. This apparatus is emptied of air, as already described; the air is rejected through the inverted syphon as before. Then by manipulating *b* the lead tube is cut; the gas in J passes into the reservoir A, the mercury in which has been lowered by depressing B. In this way the residual niton in such applicators may be recovered. In the case of a glass capillary, as in Fig. 3, it may be introduced into the apparatus of Fig. 5, the upper end of which is closed with a glass plug. The thin-walled capillary is easily broken and its contents recovered, as described.

FIG. 5.



"Strength" of Niton Generated.

As a rough guide, it may be taken that every cubic centimetre of mixed oxygen and hydrogen gases corresponds to niton of equal "strength" to 10 mgm. of radium bromide. But it depends on its age. For example, if instead of drawing gas from 500 mgm. of radium bromide after 24 hours' standing it had been drawn after 12 hours, the amount obtained would, of course, have been the fourteenth part of 25, or 1·8 c.c. But this would contain the niton generated in 12 hours, and by referring to the curve it is seen to be 0·08 of the total—that is, it is the quantity in equilibrium with 500 × 0·08, or 40 mgm.: and to get at the "strength" in radium units, multiplying by 0·75, it is in actual "strength" at the time of drawing equal to 30 mgm. It is evident, therefore, that the oftener the niton is "drawn" the more advantageous; and this is an argument in favour of having a central "institute," where a large supply of radium is kept and from which frequent drawings of niton can be made, rather than to parcel it out in small quantities and have to be contented either with weak doses, or to have to wait long for a strong dose at considerable pecuniary sacrifice. The apparatus here described can be had from Messrs. Baird and Tatlock, 14, Cross-street, Hatton Garden, London, E.C.

MEDICINE AND THE LAW.

A Case of Unqualified Practice.

AT the Worcester county court on May 13th the Society of Apothecaries recovered a penalty of £20 against Charles Burden, herbalist, of Bridge-street, Worcester, for a breach of the Apothecaries Act, 1815, in that he had acted and practised as an apothecary or medical practitioner in attending and medically treating Mrs. Rosina Daniels, of Ombersley-road, Worcester, whose death in February last was the subject of an inquest conducted by the Worcester city coroner.[1] It appeared from the evidence that Mrs. Daniels had died from Bright's disease and that she had been visited and attended by the defendant and supplied by him with herbal medicines for some months previously to her death, the defendant having informed Miss Daniels, the daughter of deceased, that he believed she had an internal abscess and that the medicine he was giving her was bringing the poison out. The deputy judge in the course of his judgment said as to the definition of an apothecary he felt bound to accept that given by Mr. Justice Cresswell in the case of the Apothecaries Company *v.* Lotinga—viz., that an apothecary was a person who professed to judge internal disease by its symptoms and applied himself to cure it by medicine. The second question was, Did the defendant act and practise as an apothecary? On that the evidence was all one way. The evidence of Miss Daniels that the defendant treated her mother, felt her pulse, and supplied her with medicine was entirely borne out by defendant. Judgment with costs was accordingly given for the society, and a stay of execution granted for 21 days, money to be paid into court within 14 days.

Coroners' Inquests and the Insurance Act.

In opening an inquest recently in the City the coroner, Dr. F. J. Waldo, told the jury that he had received a circular letter from the Home Secretary inviting coroners to give notice to the Insurance Commissioners if they had reason to believe that at an inquest about to be held questions might be raised affecting the relations between an insured patient and a medical man on the panel, or otherwise connected with the Insurance Act. It was intimated that if opportunity was given the Insurance Commissioners might desire to be represented at the inquest. At the inquest in question the fact that the medical practitioner on whose list the deceased had been had not attended at once when summoned gave rise to discussion as to the scarcity of medical men in the City. The gentleman in question had not understood that the summons was an urgent one. He stated that he believed that he was the only member of the panel residing in the City, although others attended there in the day-time and lived elsewhere. Mr. Gilbert, representing the National Insurance Commissioners, pointed out that the question where a medical practitioner lived did not affect his obligations under his contract. He had to make arrangements whereby his patients could be attended at all times.

A Parent and Medical Treatment for his Child.

The St. Helens education authority recently summoned with success a brakesman, earning 35s. per week, for 1s. 6*d.* claimed from him for medical treatment of his child at the school clinic. The summons was under Section 13 of the Administrative Provisions Act, 1907, and Section 1 of the Local Authorities *Medical* Treatment Act, 1909, the first enabling the treatment of the child to be provided for, and the second authorising the recovery of the cost from the parents. The charge was in respect of the filling of two teeth, the necessity for which the father denied. It was pointed out that at the barest cost price for what had been done the defendant might have been charged at least 4*s*. 6*d*. The defendant denied that he had been told there would be a charge made, but he had signed the consent book in which the conditions were set out. It was also pointed out that he might have had the child treated privately, and that if he had refused to do this after refusing to have her treated in the school clinic he would have been liable to proceedings under the Children Act for causing her unnecessary suffering. The magistrates ordered the defendant to pay the 1s. 6*d*. claimed, with 8*s*. 6*d*. towards the costs. He was also informed that he might have been called upon to pay the whole of the costs, amounting probably to at least £5.

---

[1] THE LANCET, Feb. 21st, 1914, p. 551.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on May 14th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following Members who had been elected to the Fellowship at the last meeting were admitted as Fellows:—Dr. Cuthbert Henry Jones Lockyer, Dr. William Mitchell Stevens, Dr. Arthur Stanley Barnes, Dr. James George Taylor, Dr. Dudley William Carmalt-Jones, Dr. Samuel Alexander Kinnier Wilson, Dr. Hector Charles Cameron, Dr. John Foster Gaskell, Dr. Gordon Morgan Holmes, Dr. Frederick Gowland Hopkins, Sir Alfred Henry Keogh, and Sir William Boog Leishman, F.R.S.

Diplomas in Tropical Medicine and Hygiene were granted, in conjunction with the Royal College of Surgeons of England, to the following candidates:—Vivian St. John Croley, Gordon Gray Jolly (Captain, I.M.S.), Maharaj Krishna Kapur, and Andrew Murphy (Major, I.M.S.).

A sketch of the late Sir Samuel Wilks was presented to the College by Dr. F. G. D. Drewitt. The thanks of the College were returned to the donor.

The following communication was received: From an Interdepartmental Committee which is considering legislation consequent on the provisions of the International Opium Convention (1912), asking the opinion of the College concerning certain limitations to the sale of opium, morphine, heroine, cocaine, &c. The matter was referred to the Censors' Board.

Dr. NORMAN MOORE proposed, and Dr. FREDERICK TAYLOR seconded, that a committee should be formed to report upon recent alterations in anatomical nomenclature. The proposal was adopted, the nomination of the members of the committee being left to the President.

A report was received and adopted from the committee appointed to consider a letter from the Board of Control concerning grants to aid scientific research in the subject of mental disease. The report was as follows:—

> The committee is of opinion that these grants should be paid to a few thoroughly trained observers, and that these persons and the nature of their investigations should be selected and approved by a small competent advisory committee appointed by the Board of Control.
>
> The committee is strongly of opinion that no grant should be allocated to municipal bodies or county councils for the purpose of subsidising or of maintaining pathological laboratories, or of paying assistants to do routine work.
>
> The committee recommends that the grants should be devoted to the study of such fundamental problems concerning insanity and mental deficiency as require scientific investigation from the clinical, pathological, biological, and sociological aspects.

The PRESIDENT then dissolved the Comitia.

THE ROYAL SOCIETY CONVERSAZIONE.

THERE was a distinguished company present at the Royal Society conversazione, which was held at Burlington House on May 13th. Sir William Crookes, O.M., D.Sc., the President, received the visitors, who showed an evident interest in the variety of scientific exhibits chosen for the occasion. Physics and biology were more strongly represented, perhaps, than other departments of science, and there was a notable absence of electrical demonstrations which for so many recent years have provided a favourite topic.

There was little shown of direct medical interest, if we except the demonstrations for which Professor Leonard E. Hill, Professor A. F. Stanley Kent, and Mr. H. G. Plimmer were respectively responsible. Professor Leonard Hill, together with his assistant, Mr. O. W. Griffith, exhibited the caleometer, an instrument designed to measure the degree of comfort in a room or a public hall or factory in so far as that depends upon the rate of cooling of the human body. A "coil" made of a wire having a temperature coefficient forms one arm of a Wheatstone's bridge, the other arms of which are made of an alloy the electrical resistance of which does not vary with the temperature. The bridge is balanced when the temperature of the "coil" is approximately that of the human body, the current being supplied from accumulators or from the main circuit. Any tendency to a variation of this temperature is checked by an automatic rheostat worked by a relay, so as to diminish the current when the temperature rises and *vice versâ*. By means of an indicator the number of calories supplied per minute to the coil to keep its temperature constant is shown at any instant. Comfortable conditions are indicated by gentle oscillations of the pointer about a mean value of 30 calories per minute. A low steady reading denotes monotony and oppressiveness, while violent oscillations about a mean value are evidence of excessive cooling by an unpleasant draught. Professor Stanley Kent exhibited specimens showing the existence of muscular continuity between the right auricle and the right ventricle in the heart of man. The structures illustrated lie at the junction of the right auricle and right ventricle at the right lateral margin of the heart. The ventricular fibres concerned are derived from two systems: (*a*) fibres ascending vertically from the direction of the apex immediately under the endocardium; and (*b*) fibres running obliquely inwards from the middle layers of the ventricular wall. Both of these sets of fibres become connected with a rounded mass of auricular substance, which differs markedly in structure from auricular tissue, and resembles the tissue found in the sino-auricular and the auriculo-ventricular nodes. Mr. Plimmer showed an interesting collection of parasites which were either new or found in new hosts. Amongst these were toxoplasma in the blood of fossa, and also in the blood of the blue-tailed fruit pigeon; myxobolus from the gall-bladder of a giant toad; intestinal organisms in the blood of ambiona box-tortoise, showing parasitic adaptation; microscopic sarcosporidia in the muscles of a langur; mycosis from the lung of a Brazilian tortoise of aspergillar form; coccidia in intestinal epithelium of a dhole and babesia in the blood of another dhole (*Nagpur*).

Messrs. Chance Brothers and Co., of Oldbury, Birmingham, exhibited an interesting series of glasses designed for spectacles for the absorption of ultra-violet and infra-red rays and for the reduction of glare. The experimental results so far as they have gone were the subject of a recent paper read before the Royal Society by Sir William Crookes. Mr. W. A. Douglas Rudge showed an interesting experiment illustrating the phenomenon of electrification produced during the raising of a cloud of dust. It appears that considerable charges of electricity are produced. A charge of one sign is found upon the dust itself and another charge of opposite sign either upon the air or else upon fine particles of dust which remain suspended in the air. Generally dust of an acidic nature—*e.g.*, silica—gives a negative charge to the air, while metallic oxides and organic bases give positive charges. It would be interesting to learn whether this phenomenon is by any chance connected with the initiation of dust explosions in coal mines, flour mills, and so forth. Professor E. W. MacBride and Mr. H. G. Newth showed specimens of double tadpoles of the frog and also double sea urchins. According to these observers the duplicity in the frog larvæ is of varying degree and was produced experimentally. Fertilised eggs were inverted immediately upon the completion of the first cleavage furrow, and were kept inverted till gastrulation was complete. The apparatus and technique employed were included in the demonstration. The duplicity in the sea-urchin larvæ consists in the development of an urchin-rudiment on both sides or of pedicellariæ on both sides, whereas the normal larva has its rudiment on the left and its pedicellariæ on the right. The Meteorological Office authorities exhibited some aneroid and mercury barometers with centibar and millibar graduation. They also displayed a chart giving a hundred years' of rainfall in the London district. The rainfall for each month from Jan. 1st, 1813, to Dec. 31st, 1912, is thus recorded. The Hon. R. C. Parsons exhibited an ingenious apparatus for automatically mixing in definite proportions one liquid with another. The application of this "chemical ejector" to the purification or softening of water-supplies is giving remarkably uniform results.

During the evening demonstrations were given in the meeting room by Professor J. P. Hill, who delighted his hearers with an account of the Percy Sladen Expedition to Brazil, 1913, and by M. P. Schilowsky, who brought the subject up to date in regard to the application of the gyroscope to locomotion on land, on sea, and in air. The extraordinary stabilising property of the gyroscope was illustrated in a most interesting way.

SUGGESTED REFORM OF MEDICAL EDUCATION IN CHINA.

Dr. Wu Lien Teh, better known to English readers as Dr. G. L. Tuck, has recently presented, in his official capacity as medical officer to the Chinese Foreign Office at Harbin, an interesting memorandum on the present status of medical education in China[1] in which he urges thorough reform.

After a brief reference to his observations at the International Medical Congress in London and the International Congress of School Hygiene at Buffalo, U.S.A., which he attended on behalf of the Chinese Government, Dr. Wu Lien Teh lays down the principle that to improve and further the best interests of medical science and education so that the graduates of the Chinese medical colleges may have the same standard of efficiency and ideals as those of the West, it is essential that the institutions where medical education is given and the hospitals where the sick are cared for and the students learn their clinical work should be in the hands of men who themselves have worked in, and are thoroughly acquainted with the management of, the best medical schools and hospitals of the West.

The Present Status of Medicine in China.

As to the present status, he points out that, in spite of some excellent methods of treatment and a long list of useful drugs handed down in China by the ancients, nothing has been done by their successors to improve knowledge or to keep abreast of the times; consequently the majority of native trained physicians to-day are completely ignorant of the true causes of most diseases, especially epidemic diseases, of their diagnosis, rational treatment, and prevention; while many diseases, such as malaria and internal abscesses, blindness from cataract, regarded by the ancients as incurable, are still so regarded, though to Western-trained practitioners they yield to very simple methods. Typhus fever, relapsing fever, leprosy—the scourges of China—have almost been wiped out in Western lands, and even syphilis, in which the same drug (mercury) is used in both East and West, Western results are better because Western methods are more accurate and scientific.

The author further points out that owing to lack of sufficient training at home, men possessing medical qualifications of Government institutions in China have to undergo the ordinary students' course of five years' instruction before they can obtain a degree at a foreign medical school, the training in China counting for nothing in a Western country; and even in the matter of Chinese Government appointments—health and customs officers, railway surgeons, &c.—medical men of other countries enjoy a higher social standing and greater privileges than native ones.

Existing Facilities for Medical Education in China.

The existing facilities for medical education in China are of three kinds:

1. Government medical colleges—viz., the Peiyang Medical College, Tientsin, founded 20 years ago by the Viceroy Li Hung Chang; and the Army Medical College, also at Tientsin, founded ten years ago by the present President, Yuan Shih Kai. The Canton Army Medical College, established some years ago, was recently closed, being unsatisfactory in consequence of insufficient staff and equipment.

2. Missionary colleges, at which diplomas are granted after four or five years' training. The medical teaching of these colleges, in accordance with a decision of the Triennial Missionary Medical Conference in 1913, is now to be centralised in eight large cities—viz., Mukden, Peking, Tsinanfu, Chengfu, Hankow, Nanking (or Hangchow), Foochow, and Canton.

3. Institutions controlled by foreign governments or corporate bodies where Chinese students can obtain a medical training—viz., the German Schools in Shanghai (1908) and Tsingtau (1911), the Harvard Medical School, Shanghai (1912), the Japanese Medical School, Mukden (1912), and the Hong-Kong University (British, 1911), of which last the medical faculty pre-existing the university is the oldest and most important.

Suggested Coöperation of the Government with the Mission Colleges.

Inasmuch as the cost of establishing an up-to-date medical college with adequate staff and equipments is, in the present state of Chinese finances, out of the question, the author suggests that the Government should avail itself of the opportunities held out by the mission colleges.

At the Missionary Medical Conference above referred to resolutions were passed affirming that, as the sole object of these colleges was to aid the Chinese people by providing a thorough training for natives in medicine and surgery, there was no desire to retain them as permanently foreign institutions, but it was rather purposed to hand them over ultimately to the Chinese themselves. Consequently, it was desired to bring their teaching into line with the regulations of the Ministry of Education and to coöperate with the Government.

As the Union Medical College at Peking is situated at the seat of government, has its organisation almost complete, and has for years been subsidised with monetary grants, while its graduates have been recognised by the Board of Education of the Ching Dynasty, the author therefore suggests that the Government and this college should endeavour to arrive at a mutually advantageous scheme of coöperation as an experiment. If successful the Government could then coöperate with the medical institutions in other large centres which had proved themselves efficient.

A Central Medical Council.

The author also suggests the establishment of a central governing body, the Central Medical Council, to which the Board of Education should delegate its power in regard to medical education. This council should consist of an official of the Board of Education, with one representative from each of the medical schools in China approved by the Board, and perhaps power to coöpt one or more leading medical men who have contributed to the promotion of medical science in the country. The duties of this council would be to determine what language or languages shall be used for medical teaching, to fix a minimum standard of preliminary education and a minimum medical curriculum, to supervise examinations and perhaps act as a central examining body for the whole country, to recognise schools other than those already recognised by the Board of Education, as well as hospitals for clinical teaching, to draw up and enforce laws relating to the practice of medicine, to issue a medical register, and to adopt a general nomenclature of medical terms in Chinese.

---

[1] Memorandum to the Board of Education (in Peking) on Medical Education in China. By Wu Lien Teh, M.A., M.D. Cantab. Reprint from the China Medical Journal, Shanghai, March, 1914.

Proposed Curriculum.

The scheme of education suited, in the author's opinion, to the needs of the country might be something as follows:—

A. Preliminary examination in general education, consisting of (1) classical Chinese; (2) a working knowledge of English, German, or French, with the outlines of history and geography of Europe and Asia, with special reference to China; and (3) mathemathics—arithmetic, geometry (Euclid I. to IV.), algebra, with easy quadratic equations. Such an education can be obtained at present at the higher Government and missionary colleges to be found in most of the large cities. These colleges might be enlisted in the propaganda for a medical career, and scholarships and prizes should be offered.

B. Medical education. This should consist of five years, each year having a three months' summer and a six months' winter session. In the first year there would be lectures and practical work in botany, zoology, chemistry, and physics, and lectures in elementary anatomy, with examinations at the end of each session. The second year would include practical anatomy with dissection of the whole body, and histology and anatomical demonstrations; lectures and practical work in physiology and practical chemical physiology, with an examination in anatomy and physiology at the end of the year. The third year would be occupied with morbid histology, pathology, and post-mortem work, bacteriology, materia medica, and therapeutics, out-patient surgical dressing, and clinical surgery, with an examination at the end of the year in pathology, bacteriology, and materia medica. The fourth year would include clinical surgery, medicine, and gynæcology, and attendance on midwifery cases during the summer holidays, with lectures on midwifery and gynæcology, medical jurisprudence, public health, and tropical medicine, and would close with an examination in midwifery, gynæcology, forensic medicine, and public health. The fifth (final) year would be devoted to infectious diseases, diseases of the eye, skin, ear, nose, and throat, and dispensary practice in the summer session; and in the winter to lectures and clinical work in medicine and surgery, vaccination, and dispensary practice. This would be followed by the final qualifying examination in medicine and surgery.

The importance of allowing dissections has to be emphasised by the author, because of the great objection thereto consequent on the ancestor worship of China. But, as he points out, the same objection was raised to the first railways in China, owing to their entailing the removal of graveyards, and opposition on this score has now been removed. Moreover, the Japanese, who hold similar religious beliefs to the Chinese, have allowed dissections and post-mortems since they adopted Western medicine, and their medical graduates are now equal to any in the world. Arrangements for post-graduate study and facilities for foreign study are also urged.

The Language of Medical Teaching.

On the question of the language to be used in teaching, inasmuch as foreign teachers will necessarily have to be employed for a long time yet to supplement the limited supply of Chinese Western graduates, and since a working knowledge of Chinese cannot be attained without years of preparation, the adoption of English is suggested on the grounds that "Western scientific workers are practically unanimous that during the coming years the greatest advances in medicine will be made in America," and also that English is more commonly used in China than any other foreign language.

The Hospitals and Medical Education.

In discussing the relation of the hospitals to medical education, some very sound observations are made. Simpler and less expensive buildings than those seen in America are considered sufficient. Hospitals associated with teaching schools form so integral a part of medical education that they must be considered as actual departments of such schools, being built to suit the needs of the various branches of medical science, and their senior physicians and surgeons being *ipso facto* heads of their respective departments in the University. The proper working of the hospital in regard to patients should be carried out entirely without the help of the student, whom it should serve simply as an institution for instruction. If the care of patients depends for efficiency in any degree on the student it will militate against its proper use as a means of instruction for him. The hospital must also assist the student to a conception of surgical cleanliness, carefulness and accuracy of observation, discipline, sympathy, and humaneness.

Western versus Oriental Medicine.

In concluding, the author points out the absurdity and expensiveness of maintaining two systems of medicine. "Either modern medical methods are superior to the old methods or the old methods are superior to the modern. If old methods are better they should be retained and the modern methods abolished. If, on the other hand, modern methods are better—and this has been proved in all up-to-date countries, including Japan, whose people used to have the same ideas as ours—they should be wholly adopted, and steps should be taken for a gradual merging of the old into the new one."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on May 14th, Sir RICKMAN GODLEE, the President, being in the chair.

Surgeon-General Arthur William May, C.B., R.N., was introduced, and after signing the by-laws and making the required declaration, was admitted a Fellow of the College.

Mr. J. Howell Evans was introduced, and the PRESIDENT handed to him a cheque for the amount of the Jacksonian prize, together with a document declaratory of the award.

It was resolved to issue diplomas of Membership to 104 successful candidates. It was resolved to grant diplomas of the Licence in Dental Surgery to 41 successful candidates. It was resolved to grant, in conjunction with the Royal College of Physicians of London, diplomas in Tropical Medicine and Hygiene to four successful candidates.

Mr. C. A. Ballance was re-elected a member of the Court of Examiners.

A letter was read from Mrs. Bruce Clarke thanking the Council for their resolution of condolence on the death of her husband.

The PRESIDENT reported that he had accepted a pencil sketch of Thomas Wormald, President of the College in 1865, presented by his sister, Mrs. Leighton, through Sir Berkeley Moynihan, together with a plate of drawings by Sir Charles Bell from a very early case in which vaccination was performed. The best thanks of the Council were accorded to Mrs. Leighton for her gift. A letter was read from Mr. Clement Lucas resigning his seat on the Council. The resignation was accepted, and the Council expressed their regret that the state of his health should cause him to sever his official connexion with the College, and the PRESIDENT stated that the vacancy so occasioned would be filled up at the annual meeting of Fellows in July.

It was resolved, in accordance with a report from the Board of Examiners in Dental Surgery, that the First Professional Examination be held three times a year, commencing in the third or fourth week of January, April, and September, and that the Second Professional Examination be held three times a year, in February, towards the end of May or early in June, and in November.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the thirty-fourth meeting of the Royal Commission on Venereal Diseases evidence was given by Dr. M. H. Frances Ivens, honorary medical officer for diseases of women at the Liverpool Stanley Hospital, honorary surgeon to the Samaritan Hospital, and honorary medical officer to the Liverpool Maternity and Rescue Homes. Dr. Ivens said that her experience in Liverpool led her to the conclusion that gonorrhœa in women was extremely widespread in that town. Investigations which she had made in the years 1907 to 1909 respecting the incidence of gonorrhœa in gynæcological hospital practice showed that of 1052 consecutive out-patients 149, or 14 per cent., suffered from gonorrhœa, and of these 47, or 30 per cent., were sterile; of 153 in-patients 39 had gonorrhœa, or 1 in 4, and of these 13, or 33 per cent., were sterile.

Dr. Ivens said that the disease was difficult to cure completely and that relapses were frequent. Reinfection was also very common, and was the cause of much disappointment after prolonged treatment. This raised the important question whether in the case of a married woman the patient should be informed of the true nature of the disease from which she was suffering. At the present time it was the custom in the medical profession to conceal the nature of the disease from the wife in order to avoid causing mental worry in addition to physical illness. Dr. Ivens said that the question was a difficult one, but she doubted whether the present attitude in this matter was correct. It was manifestly unfair that a woman should be subjected to repeated reinfection without her consent, and if unaware of the nature of the disease she was unlikely to submit to efficient treatment. If any change were to be made by the medical profession in this matter it must be made by the profession as a whole.

At the thirty-fifth meeting evidence was given by Professor F. W. Andrewes, pathologist at St. Bartholomew's Hospital, and Miss Gregory, honorary secretary of the Home for Mothers and Babies, Woolwich. Professor Andrewes's evidence dealt mainly with the subject of the results of syphilis in the production of arterial disease. There were, he said, several diseases of the blood-vessels and the heart commonly fatal in their result, and by no means rare, which were not obviously syphilitic in nature, and did not figure as results of syphilis in death returns, but which were now recognised as late results of syphilis. The main object of his evidence was to draw attention to the commonness and gravity of these indirect and late results of syphilis.

Miss Gregory said that she was anxious to impress upon the Commission the necessity for every pupil midwife receiving a short course of lectures on venereal diseases and clinical instruction at a lock hospital. At the present time she thought midwives were absolutely ignorant in these matters. It would be impossible to include such a course of lectures in the present syllabus, and she would not advocate it unless the whole training were lengthened; at present the period allotted by the Central Midwives Board for training was the wholly inadequate one of three months.

APRIL AT HOME AND ABROAD.

At Home.

FOLLOWING the example of February and March, April continued to bring rain in great or small quantities nearly every day until about the 12th, when it suddenly changed its character and gave one of the brightest and driest spells that this country has experienced for a very long period. For about three weeks there was no rain whatever over a large portion of England, and in Scotland and Ireland the falls were extremely slight and few. The temperature, too, which had not been low during the unsettled opening of the month, rose very appreciably, and many parts of the kingdom recorded shade maxima as high as 70°, while most of the nights were fairly mild, and frost severe enough to injure the profuse blossom covering the fruit trees was very restricted in its area. Over the country generally the mean temperature for the month was 3° or 4° above the average, and the sunshine between two and three hours per day in excess, while in numerous localities the aggregate rainfall was less than half the normal. At Kew the mean maximum temperature was as high as 59°, or 5° above that of a normal April, and the mean minimum, 41°, exceeded the normal by 1°. The total number of hours of sunshine was a trifle above 220, and represented an excess of more than two hours per day, while the rainfall, 0·61 in., was as much as 0·85 in. below the average. Some other parts of the metropolitan area were, relative to their average, brighter than Kew. At Westminster the total number of hours of sunshine was 216, giving an excess on the average of nearly 3½ hours per day, while at Greenwich the aggregate was as high as 232 hours. Both Bath and Nottingham were slightly warmer than Kew during the daytime and a little colder at night, and at Bath the days were brighter, yielding the large aggregate of 241 hours of sunshine, an excess of three hours daily. Nottingham was also very bright, with 224 sunny hours, and at Birmingham the figure was nearly 210 hours. Along the coast to the south and west the duration of sunshine was, as it is generally, more liberal than elsewhere. About 230 hours was a common total along the south coast. At Torquay there was as much as 237 hours, and at Newquay and the Scilly Isles 20 hours more. Jersey, however, was hardly so bright, its total sunshine scarcely exceeding that at Nottingham. The most equable temperature was at Scilly, where the mean maximum was 56° and the mean minimum 46°, but the range between the warmth of the day and night was only 13° or 14° at Jersey, Newquay, and Torquay, against 18° in London and 21° in the Midlands. Over the country as a whole the brightest and warmest period of the month was a week or so from the 14th, when a cloud was a rarity, and the thermometer mounted to 70° or a little higher. Considered generally, last month was the finest April for many years. Probably none since 1893 has given so many bright, dry days.

Abroad.

All the adjacent countries of the continent shared in the fine weather. At Paris rain fell on only nine days, giving the small total of 0·9 in., while the sunshine was 252 hours, about an hour per day longer than at Kew, the mean maximum temperature was as high as 65°, and the mean minimum 44°. Berlin and Vienna were both less warm than Paris, their respective mean maximum temperatures being 60° and 62° and the mean minima 43° and 42°. Both cities were dry, having little or no rain after the 10th, although their total fall was much higher than in London, the figure being about 1·3 in. The Riviera had practically no rain until the 30th, and at Biarritz rain only fell on seven days. Southern France generally was rather warm for the time of year. At Nice the shaded thermometer rose to 70° or above on several occasions, and the mean maximum was as high as 67°, exceeding that at Biarritz by 3°. The mean minimum, however, 50°, was the same at both resorts, Biarritz thus living up to its character of being more equable than the resort on the Riviera. Throughout Italy the weather was almost continuously fine and dry, rain falling on very rare occasions, and the thermometer pointing to readings which would be considered seasonable in southern England during June. At Rome only four days brought slight rain, and the mean maximum temperature was no lower than 69°. The nights were relatively cool, giving a mean minimum temperature 2° lower than Nice and Biarritz, and only 2° above that at Scilly and Jersey.

The change to dry weather after more than two months of more or less rain nearly daily was due to barometric pressure assuming an anticyclonic distribution in this part of the world in place of the cyclonic condition that is the more usual. Ever since the latter part of January the Atlantic had passed on depression after depression to these islands or their immediate vicinity, but the system which threatened to give a rainy Easter was the last of the series, and during the next three weeks two large anticyclones, which also came from the Atlantic, ruled the weather as they moved in a leisurely manner across the British Isles and the North Sea to the continent. An anticyclone in spring usually gives colder easterly winds in the south of England than those of last month, and is too often accompanied by sharp frost at night. On this occasion the wind had but a moderate cutting capacity, and, considering the many cloudless nights, frost was uncommon.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 9245 births and 4905 deaths were registered during the week ended Saturday, May 16th. The annual rate of mortality in these towns, which had been 15·1, 14·2, and 14·1 per 1000 in the three preceding weeks, was again 14·1 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 14·6, against 15·8 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 2·8 in Eastbourne, 6·3 in Cambridge, 6·8 in East Ham, 7·4 in Ilford, and 7·5 in Southend-on-Sea, to 20·1 in Stoke-on-Trent, 20·4 in Tynemouth, 20·5 in Gateshead, 21·7 in Carlisle, and 23·1 in Dudley and in Middlesbrough.

The 4905 deaths from all causes were 9 in excess of the number in the previous week, and included 421 which were referred to the principal epidemic diseases, against 453 and 436 in the two preceding weeks. Of these 421 deaths, 143 resulted from whooping-cough, 138 from measles, 69 from infantile diarrhœal diseases, 33 from scarlet fever, 31 from diphtheria, and 7 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·2, against 1·3 per 1000 in each of the four preceding weeks. The deaths attributed to whooping-cough, which had been 166, 139, and 146 in the three preceding weeks, fell to 143 last week, and caused the highest annual death-rates of 1·3 in Sheffield, 1·4 in Warrington, 1·7 in Hastings and in Gateshead, 1·8 in Bury, and 2·2 in Walsall. The deaths referred to measles, which had been 140, 155, and 146 in the three preceding weeks, further declined to 138 last week; the highest death-rates from this cause were 1·3 in Salford and in Swansea, 1·4 in Smethwick, in Bootle, and in Burnley, 1·5 in Sheffield, 1·7 in Rochdale, and 2·0 in Dudley. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 66, 59, and 59 in the three preceding weeks, rose to 69 last week; of this number 18 were registered in London, 7 in Liverpool, 5 in Birmingham, and 3 each in Nottingham, Manchester, Leeds, and Middlesbrough. The deaths attributed to scarlet fever, which had been 23, 35, and 27 in the three preceding weeks, rose to 33 last week, and included 8 in London, 4 in Liverpool, 4 in Sheffield, and 2 each in Birmingham, Manchester, Oldham, and Newcastle-on-Tyne. The deaths referred to diphtheria, which had been 40, 50, and 44 in the three preceding weeks, further fell to 31 last week; 5 deaths occurred in London, 3 in Birmingham, 3 in Manchester, and 2 each in Bristol, Bolton, and Rotherham. The fatal cases of enteric fever, which had been 10, 15, and 13 in the three preceding weeks, fell to 7 last week, of which 2 were recorded in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 2886, 2876, and 2901 at the end of the three preceding weeks, had declined to 2862 on Saturday last; 349 new cases were admitted during the week, against 305, 377, and 398 in the three preceding weeks. These hospitals also contained on Saturday last 1129 cases of diphtheria, 356 of whooping-cough, 110 of measles, and 44 of enteric fever, but not one of small-pox. The 1157 deaths from all causes in London were 39 fewer than the number in the previous week, and corresponded to an annual death-rate of 13·4 per 1000. The deaths referred to diseases of the respiratory system, which had been 258, 185, and 221 in the preceding three weeks, declined to 191 last week, and were 19 below the number registered in the corresponding week of last year.

Of the 4905 deaths from all causes in the 97 towns, 174 resulted from different forms of violence, and 381 were the subject of coroners' inquests, while 1429 occurred in public institutions. The causes of 39, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, and in 56 other smaller towns. Of the 39 uncertified causes of death, 6 were registered in Birmingham, 3 in Stoke-on-Trent, 3 in Liverpool, 3 in Sunderland, and 2 each in Gillingham, Southend-on-Sea, Coventry, Bootle, Preston, Sheffield, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1230 births and 673 deaths were registered during the week ended Saturday, May 16th. The annual rate of mortality in these towns, which had been 16·9, 15·2, and 16·2 per 1000 in the three preceding weeks, declined to 15·3 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 16·0, against a corresponding rate of 14·6 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 7·6 in Motherwell, 10·9 in Paisley, and 12·1 in Dundee, to 18·2 in Coatbridge, 22·0 in Ayr, and 23·4 in Clydebank,

The 673 deaths from all causes were 40 fewer than the number in the previous week, and included 56 which were referred to the principal epidemic diseases, against 61 and 64 in the two preceding weeks. Of these 56 deaths, 20 resulted from measles, 18 from whooping-cough, 6 from infantile diarrhœal diseases, 5 from diphtheria, 4 from scarlet fever, and 3 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3, against 1·2 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 29, 19, and 31 in the three preceding weeks, fell to 20 last week, of which 13 occurred in Glasgow, 2 in Edinburgh, and 2 in Dundee. The deaths referred to whooping-cough, which had been 9, 13, and 17 in the three preceding weeks, were 18 last week, and included 9 in Glasgow, 3 in Coatbridge, and 2 in Falkirk. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 18, 17, and 4 in the three preceding weeks, rose to 6 last week, and included 2 in Glasgow and 2 in Dundee. The deaths attributed to diphtheria, which had been 9, 8, and 7 in the three preceding weeks, further fell to 5 last week, but showed no excess in any town. The 4 deaths referred to scarlet fever, of which 3 occurred in Glasgow and 1 in Kirkcaldy, were slightly below the average in the earlier weeks of the quarter. Of the 3 fatal cases of enteric fever, 2 were registered in Glasgow and 1 in Kilmarnock.

The deaths referred to diseases of the respiratory system, which had been 130, 90, and 116 in the three preceding weeks, declined to 104 in the week under notice; and 23 deaths resulted from various forms of violence, against numbers declining from 31 to 16 in the three preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 677 births and 421 deaths were registered during the week ended Saturday, May 16th. The annual rate of mortality in these towns, which had been 25·3, 20·6, and 18·6 per 1000 in the three preceding weeks, further fell to 18·2 per 1000 in the week under review. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 20·9 per 1000; in the 97 large English towns the corresponding rate did not exceed 14·6, while in the 16 Scotch towns it was equal to 16·0 per 1000. The annual death-rate last week was equal to 19·5 in Dublin (against 13·4 in London and 16·7 in Glasgow), 17·6 in Belfast, 21·1 in Cork, 12·7 in Londonderry, 10·8 in Limerick, and 19·0 in Waterford, while in the 21 smaller towns the mean rate was 18·1 per 1000.

The 421 deaths from all causes were 10 fewer than the number in the previous week, and included 43 which were referred to the principal epidemic diseases, against numbers steadily declining from 75 to 47 in the four preceding weeks. Of these 43 deaths, 21 resulted from measles, 9 from infantile diarrhœal diseases, 8 from whooping-cough, 2 from scarlet fever, 2 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·9, against corresponding rates of 1·2 and 1·3 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 37, 45, and 30 in the three preceding weeks, further declined to 21 last week, of which 17 occurred in Dublin and 3 in Belfast. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had declined from 10 to 3 in the four preceding weeks, rose to 9 last week, and included 5 in Dublin and 3 in Belfast. The fatal cases of whooping-cough, which had fallen from 14 to 9 in the four preceding weeks, were 8 last week, of which 5 were recorded in Belfast. The 2 deaths from scarlet fever were recorded in Belfast, and were 2 below the average in the earlier weeks of the quarter. The fatal cases of diphtheria occurred in Lisburn and Kilkenny, and that of enteric fever in Dublin.

The deaths referred to diseases of the respiratory system, which had declined from 115 to 74 in the four preceding weeks, rose to 86 in the week under notice. Of the 421 deaths from all causes, 132, or 31 per cent., occurred in public institutions and 12 resulted from various forms of violence. The causes of 16, or 3·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

ASYLUM WORKERS' ASSOCIATION.—At the annual meeting of this association, which was held on May 20th, at the Medical Society's House, Chandos-street, W., under the presidency of Sir John Jardine, K.C.I.E., M.P., it was stated in the annual report that there had been a falling off in membership. Reference was made to the Mental Deficiency Act, 1913, and the hope expressed that many of the workers employed under the new Act would realise the advantage of protecting their interests by joining the association. The society exists for the purpose of raising the status of asylum nurses and attendants and of promoting their general welfare. The address of the secretary is 8, Lancaster-place, Hampstead, N.W.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Staff-Surgeon John Neil Robertson has been promoted, for conspicuous professional merit, to the rank of Fleet-Surgeon in His Majesty's Fleet (dated May 15th, 1914). Surgeon James Leslie Barford has been promoted to the rank of Staff-Surgeon in His Majesty's Fleet (dated May 19th, 1914), and Surgeon Richard Connell has been promoted to the rank of Staff Surgeon in His Majesty's Fleet (dated May 14th, 1914).

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned has been appointed Surgeon: Stanley Henry Scott (dated May 15th, 1914).

ARMY MEDICAL SERVICE.

Surgeon-General Sir A. T. Sloggett, C.B., C.M.G., has been granted leave of absence until June 1st, when he will take over the duties of Director-General of the Army Medical Services from Sir William Launcelotte Gubbins, K.C.B., M.V.O., who will be retired.

ROYAL ARMY MEDICAL CORPS.

Colonel J. Maher has been appointed Deputy Director of Medical Services to the Gibraltar Command. Brevet-Colonel S. Hickson has taken up duty as Inspector of Medical Services on the Headquarters Staff at the Horse Guards.

Lieuteant-Colonel C. A. Young has been transferred from Shrewsbury to the Chatham District. Lieutenant-Colonel R. H. Hall has been appointed to the Southern Command. Lieutenant-Colonel D. M. O'Callaghan has been appointed to hold charge of the Military Hospital at Dover. Lieutenant-Colonel F. R. Newland has been appointed to hold charge of the Military Hospital at Colchester. Lieutenant-Colonel M. P. C. Holt, D.S.O., has arrived home from India. Lieutenant-Colonel B. J. Inniss has been appointed to hold charge of the Military Hospital at Delhi Cantonment. Lieutenant-Colonel N. Faichnie has been appointed Senior Medical Officer at Preston. Lieutenant-Colonel G. A. T. Bray has been appointed Senior Medical Officer in charge of the Royal Hospital, Chelsea. Lieutenant-Colonel C. W. H. Whitestone has arrived home for duty from Lahore. Lieutenant-Colonel S. G. Moores has taken over charge of the Military Hospital at Warley.

Major G. J. A. Ormsby has arrived home from India. Major J. C. B. Statham has been appointed to the London District. Major A. H. Safford has been appointed to the Eastern Command. Major W. L. Baker has been appointed to the Medical Recruiting Staff in the London District. Major W. M. B. Sparkes has taken up duty in the Sierra Leone Protectorate. Major W. L. Bennett has been transferred from Pontefract to Halifax. Major T. B. Unwin has arrived home from the Sierra Leone Protectorate. Major J. G. Gill has been appointed to the Southern Command. Major F. E. Gunter has arrived home from Meerut Cantonment. Major J. C. Kennedy has been appointed to the Military Hospital at Lucknow Cantonment. Major R. L. Popham has embarked for India. Major L. Addams-Williams has been transferred from Tidworth to Karachi Cantonment. Major H. P. W. Barrow has been appointed to the London District. Major W. J. Taylor has been appointed to officiate as Senior Medical Officer to the Sierra Leone Protectorate during the absence on leave of Lieutenant-Colonel J. J. Gerrard. Major V. G. Crawford has arrived home for duty from Mauritius. Major C. E. W. S. Fawcett has been transferred from the Military Hospital at Queenstown to the Indian Establishment. Major H. C. Winckworth has relinquished charge at Woolwich. Major S. O. Hall has been appointed to the Military Hospital at Rangoon.

Captain W. Mitchell has been appointed to the Western Command. Captain B. A. Odlum has been transferred from Simonstown to Bloemfontein. Captain D. McGrigor has joined at Agra. Captain J. Startin has been granted six months' leave of absence home from India. Captain J. J. H. Beckton has been appointed to the Military Hospital at Sialkot Cantonment. Captain J. M. M. Crawford has taken up duty at Ipswich as Adjutant to the Royal Army Medical Corps School of Instruction. Captains E. B. Booth and G. Ormrod have embarked for a tour of service in the Sierra Leone Protectorate. Captain A. H. Heslop has been appointed to the Aldershot Command. Captain A. G. Wells has arrived home from India. Captain W. J. E. Bell has taken up duty in the London District. Captain M. Keane has embarked for India. Captain D. De C. O'Grady has arrived home from India. Captain A. M. Bennett has been appointed to hold charge of the Military Hospital at Newport. Captain P. Davidson, D.S.O., has taken up duty in Aldershot as Adjutant to the Royal Army Medical Corps Depôt. Captain P. S. Stewart has arrived home from Malta. Captain J. A. Bennett has been appointed to the Military Hospital at Cork. Captain F. W. M. Cunningham has been appointed Staff-Surgeon to Headquarters at Sialkot Cantonment. Captain D. M. Corbett has been appointed to the Military Hospital at Ambala Cantonment. Captain A. W. Gater has joined the Military Hospital at Winchester. Captain W. F. M. Loughnan has arrived home from India. Captain G. A. D. Harvey has been appointed Specialist in Physical Training to the Staff of the Royal Army Medical College. Captain T. E. Harty has been appointed to hold charge of the Military Hospital at Wonkufu, West Africa. Captain E. T. Gaunt has joined at Malta. Captain A. C. Amy has arrived home from Agra Cantonment. The following captains have been placed under orders to join the Royal Army Medical College for the next session for promotion to the rank of Major:—A. E. G. Frazer, A. M. Pollard, W. B. Purdon, G. F. Rudkin, O. C. P. Cooke, J. du P. Langrishe, and W. I. Thompson. Captain M. J. Cromie has taken up duty in the Sierra Leone Protectorate. Captain E. Gibbon has joined the Egyptian Army. Captain J. R. Foster has arrived home from the Military Hospital at Neemuch Cantonment. Captain H. J. Crossley has been appointed to the Military Hospital at Bareilly Cantonment. Captain T. H. Gibbon has been appointed Pathologist to the Military Hospital at Dublin. Captain A. Hendry has taken up duty at Colaba, Bombay. Captain A. G. Cummins has been appointed to the Egyptian Army. Captain J. H. Gurley has been appointed Specialist in Ophthalmology to the Royal Victoria Military Hospital at Netley. Captain R. C. Hallowes has joined at Holywood. Captain G. F. Dawson has been appointed to the Military Hospital at Bareilly Cantonment. Captain N. E. J. Harding has been appointed to hold medical charge at the Tower of London. Captain W. D. Kelly has taken up duty at Pretoria as Specialist in Advanced Operative Surgery. Captain G. A. Kempthorne has been placed in medical charge at Tregantle. Captain C. R. Millar has joined at Ballincollig. Captain C. H. Denyer has been appointed to the Military Hospital at Agra Cantonment. Captain F. T. Dowling has been appointed to hold charge of the Cantonment General Hospital at Nowshera. Captain S. W. Kyle has joined at Jubbulpore.

Lieutenant T. A. Weston has been selected for appointment as Specialist in Advanced Operative Surgery to the Eighth (Lucknow) Division of the Northern Army in India. Lieutenant T. C. R. Archer has taken up duty at Hong-Kong. Lieutenant T. H. Balfour has been appointed to hold charge of the Military Hospital at Inverness. Lieutenant S. J. Higgins has joined at Lucknow. Lieutenant W. O. W. Ball has been appointed to the Military Hospital at Longmoor Camp. Lieutenant A. Hood has taken up duty at the Military Hospital, Rawal Pindi Cantonment. Lieutenant S. D. Large has been appointed to hold charge of the Reception Hospital at Aldershot. Lieutenant S. P. Sykes has been appointed to the Military Hospital at Jutogh Cantonment.

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers:—Lieutenant-Colonel to be Colonel: Thomas Edward Dyson (dated Jan. 10th, 1914). Captains to be Majors (dated Jan. 26th, 1914): James McPherson, George Denne Franklin, Charles Aikman Gourlay, Robert Archer Lloyd, John Conrad Gie Kunhardt, Ernest Alexander Walker, Lewis Cook, Leonard Bodley Scott, Gerard Irvine Davys, William Leigh Trafford, Howard Crossle, Edward Charles Cecil Maunsell, John Warwick Illius, and John Philip Cameron.

The promotion of James Jackson Robb and Shaik Abdur Ruzzak to their present rank of Major is antedated from Jan. 29th, 1913, to July 29th, 1912.

The King has approved the retirement of the undermentioned officers: Colonel Robert Bradley Roe (dated May 15th, 1914), Lieutenant-Colonel Joseph Rosamond Adie (dated March 22nd, 1914), and Lieutenant-Colonel Herbert Wilson Pilgrim (dated May 11th, 1914).

Surgeon-General W. Babtie, V.C., C.B., C.M.G., British Service, has been appointed Director, Medical Services, vice Surgeon-General Sir A. T. Sloggett, C.B., C.M.G., British Service (dated March 22nd, 1914).

Colonel R. Robinson has taken up duty as Assistant Director of Medical Services to the Kohat Brigade.

Lieutenant-Colonel F. J. Drury has been appointed Inspector-General of Civil Hospitals in Behar and Orissa. Lieutenant-Colonel T. W. Irvine has been appointed to hold civil medical charge at Peshawar. Lieutenant-Colonel J. G. Hojel has arrived home on leave of absence from India. Lieutenant-Colonel W. D. Sutherland has been appointed for special duty as Serologist at Calcutta. Lieutenant-Colonel J. L. Macrae has been appointed Civil Surgeon at Coorg. Lieutenant-Colonel L. F. Childe has been granted three months' extension of leave of absence home from India on medical certificate. Lieutenant-Colonel W. E. Jennings has been appointed to officiate as Assistant Director of Medical Services to the Bombay Brigade. Lieutenant-Colonel P. Carr-White has joined for duty in Nepal.

Lieutenant-Colonel J. Morwood has been appointed to Shahjahanpur.

Major W. H. Leonard has arrived home on combined leave of absence from India. Major H. B. Steen has been placed in civil medical charge at Murshidabad. Major W. W. Clemesha, Sanitary Commissioner to the Presidency of Bengal, has been allowed combined leave of absence home from India for two years. Major V. B. Bennett has been appointed to Hyderabad, Sind, as Civil Surgeon and Superintendent of the Lunatic Asylum. Major F. D. S. Fayrer has been granted two months' extension of leave of absence home from India. Major R. F. Baird has been appointed to Gonda on transfer from the Central Research Institute at Kasauli Cantonment. Major I. M. Wooley has taken up duty at Dacca as Superintendent of the Central Jail.

White has been appointed to officiate as Assistant to the Director-General. Captain C. J. Brierley has been placed on general duty in the Peshawar District. Captain O. Berkeley Hill has been transferred from Lahore to Bombay. Captain C. A. Gourlay has been appointed to officiate as Civil Surgeon at Chittagong. Captain T. C. McCombie Young has taken up duty in Assam as Deputy Sanitary Commissioner. Captain R. A. Lloyd, medical officer of the 21st Punjabis, has been appointed to officiate as Civil Surgeon and Superintendent of the Jail at Belaspur. Captain J. Forrest has been appointed District Medical and Sanitary Officer at Kistna. Captain H. M. H. Melhuish, plague medical officer in the Punjab, has been granted six months' leave of absence home from India. Captain W. J. Collinson has taken up duty as Plague Medical Officer at Meerut.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant William R. Gardner to be Captain (dated May 18th, 1914). Cadet James O'Brien, from the Royal College of Surgeons in Ireland Contingent, Officers Training Corps, to be Lieutenant, on probation (dated March 26th, 1914). Cadet Sergeant Alexander Caulfield Jebb, from the Glasgow University Contingent, Officers Training Corps, to be Lieutenant, on probation (dated April 24th, 1914). Cadet Sergeant James Couper Brash, from the Leeds University Contingent, Officers Training Corps, to be Lieutenant, on probation (dated April 17th, 1914). Cadet (late Cadet Colour-Sergeant) Francis George Macnaughton, from the Edinburgh University Contingent, Officers Training Corps, to be Lieutenant, on probation (dated April 29th, 1914).

The undermentioned officers resign their commissions (dated April 3rd, 1914): Captain Clarence E. Greeson, Lieutenant Gerald M. Graham, and Lieutenant Henry B. Parker.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd South-Western Mounted Brigade Field Ambulance, Royal Army Medical Corps: Henry Norman Barnett to be Captain (dated May 16th, 1914). John Munro Dupont to be Captain (dated May 16th, 1914).

3rd South Midland Field Ambulance, Royal Army Medical Corps: Captain Bertram M. H. Rogers to be Major (dated May 16th, 1914).

2nd London Sanitary Company, Royal Army Medical Corps: Lieutenant William A. Berry resigns his commission (dated May 20th, 1914).

For Attachment to Units other than Medical Units.—John Douglas Staley to be Lieutenant (dated Jan. 22nd, 1914). Lieutenant Charles L. Fraser resigns his commission, and is granted permission to retain his rank and wear the prescribed uniform (dated May 16th, 1914).

Attached to Units other than Medical Units.—Lieutenant Owen J. Parry-Edwards resigns his commission (dated May 20th, 1914).

ROYAL NAVY MEDICAL CLUB.

The annual dinner of the Royal Navy Medical Club was held at Prince's Restaurant, Piccadilly, on May 15th, when Surgeon-General Christopher Pearson presided. The guests of the club included Admiral H.S.H. Prince Louis of Battenberg, Vice-Admiral Sir John R. Jellicoe, Sir W. Watson Cheyne, Sir Dyce Duckworth, and Sir John Tweedy. The following members were present:—Surgeons-General: A. W. May, C.B. (Director-General Medical Department), Sir J. Porter, K.C.B. (late Director-General Medical Department), A. J. J. Johnston, J. J. Dennis, W. H. Norman, J. L. Barrington, and W. M. Craig, C.B. Inspector-General: B. Ninnis, C.V.O. Deputy Surgeons-General: G. Welch (Deputy Director-General Medical Department), P. B. Handyside, H. W. G. Doyne, G. A. Dreaper, C. J. Mansfield, M.V.O., and V. G. Thorpe. Deputy Inspector-General: F. A. Jeans. Fleet-Surgeons: P. W. Bassett-Smith, C.B., A. F. Harper, H. B. Beatty, J. Moore, D. J. P. McNabb, C. Strickland, G. T. Broatch, J. D. Hughes, G. A. Waters, J. Shand, W. A. Whitelegge, E. H. Hodnet de Courtmacsherry, R. Hill, C.V.O., F. W. Parker, R. C. Munday, A. Gaskell, E. J. Finch, M. L. F. Rodd, C. L. W. Bunton, P. H. Boyden, E. T. P. Eames, M. P. Jones, W. S. H. Sequeira, W. L. Martin, D. W. Hewitt, F. H. Nimmo, E. Sutton, G. E. Kennedy (retired), F. D. Lumley (retired), J. W. O. Underhill (retired), and J. E. Cook. Staff-Surgeons: R. W. G. Stewart, P. D. Ramsay, L. Warren, E. Cox, J. H. Rooney, H. B. Shewell, A. F. Fleming, A. K. Smith Shand, J. S. Dudding, B. Pick, and A. D. Cowburn, R.N.V.R. Surgeons: A. G. Malcolm, G. M. Levick, G. F. Syms, K. H. Hole, T. R. Lloyd Jones, H. C. Devas, H. F. Briggs, A. T. Rivers, G. A. Jackson, J. Barrett, M. P. Fitzgerald, H. W. Nicholls, Campbell Ross, F. L. Smith, E. D. Macnamara (retired), W. N. Pickles, R.N.V.R., W. F. Fedden, R.N.V.R., and P. D. Pickles, R.N.V.R.

BRITISH SCIENCE GUILD.—The annual meeting of the British Science Guild will be held at the Mansion House to-day (Friday, May 22nd), at 4 P.M., the Lord Mayor presiding. Sir Ronald Ross will deliver an address, and other speakers will include the President of the Guild, the Right Hon. Sir William Mather. The annual dinner will be held at 7 P.M. at the Trocadero Restaurant.

EDINBURGH UNIVERSITY CLUB OF LONDON.—The jubilee dinner of this club was held on May 13th in the Grand Hall of the Hotel Cecil under the chairmanship of Lord Balfour of Burleigh. There was a large company, which included many members of the medical profession. Among those who supported the chairman were Sir William Turner, M.D. (Principal of the University of Edinburgh), Sir Archibald Geikie (late President of the Royal Society), Sir Dyce Duckworth, Sir Lauder Brunton, Surgeon-General Sir Launcelot Gubbins, Sir Robert Finlay, K.C., Sir W. Watson Cheyne, Sir StClair Thomson, Sir Henry Craik, Dr. Graham Brown (President of the Royal College of Physicians of Edinburgh), Professor F. M. Caird (President of the Royal College of Surgeons of Edinburgh), Surgeon-General A. W. May (Medical Director of the Navy), Dr. Robert Farquharson, P.C., Mr. Harold Stiles, Dr. Byrom Bramwell, and Dr. J. T. C. Laing and Dr. L. F. Knuthsen (honorary secretaries of the club). The Chairman, in submitting the toast of the Edinburgh University Club of London, spoke of the loss which it had suffered through the recent death of the Duke of Argyll. Referring to the services rendered by the club to the University, he pointed out that in commemoration of its jubilee the club, which now had a membership of 600, had decided to make a contribution of £500 towards the Lister Memorial Institute of Science now being established in Edinburgh. A better tribute to one of the noblest men who had ever adorned the great profession so largely represented at that dinner could not be devised or carried out. Lord Balfour coupled with the toast the name of Sir Dyce Duckworth, the only surviving original member of the club. Sir Dyce Duckworth, in response, recalled that the club had its origin in 1854 in a group of friends who met at 77, Manchester-street. He hoped the club would always preserve the spirit of loyalty to the *alma mater*. The influence of hard work in the atmosphere of Edinburgh raised the ordinary man and left its mark on him for the rest of his days. The toast of "The Guests" was proposed in graceful terms by Sir Robert Blair, chief education officer to the London County Council. The response was entrusted to Sir William Turner, who was very warmly received. He was that night, he said, in the position of representing their academic parents, and as such he offered the club felicitations upon reaching its fiftieth year. Referring to the contribution to the Edinburgh Lister Memorial, Sir William Turner paid an eloquent tribute to the memory of Lister, whom they honoured not only as a great leader but for his personal character, for no man had a more simple, more beautiful nature: he had taken his place among the immortals. The toast was also responded to by Mr. Edmund Gosse and Mr. G. A. S. Gordon. The health of the chairman was proposed in an amusing speech by Dr. George Ogilvie, who dwelt on the varied abilities of Lord Balfour and his distinguished public services, and in particular on the advantage which it had been to him to hail from the ancient kingdom of Fife. The proceedings concluded with the chairman's reply.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 1415.)

XLVI.—COLCHESTER.

COLCHESTER is a quiet town with many fine old houses and some ruins that testify to its antiquity. It is an old-fashioned country town, and a military and social rather than an industrial centre. But there are some industries. There are, for instance, engineering and cloth works, and in connexion with the latter some difficulty is presented from the health point of view, as the number of home workers is large. A considerable portion of the work is in the making of "shoddy" clothes, given out for many miles round to cottagers. The cloth is converted into clothes in these private, unwatched, and uncontrolled dwellings. Will the well-known abuses associated with the home and piecework systems be better controlled and checked now that many of these home workers, being employed persons, are under the Insurance Act? Certain it is that already numerous cases of latent illness have been brought to the front and there is now medical treatment where formerly there was nothing but neglect.

Colchester has a population of 43,500; therefore it has not an Insurance Committee of its own, but depends on the Essex Insurance Committee. This body, as mentioned when dealing with Southend, meets in London, and the getting backwards and forwards to London for this and other committees constitutes a serious administrative difficulty. There is a local insurance area, which corresponds roughly with the North-East Essex Division of the British Medical Association, and in 1912 the practitioners in this area fought against the proposed insurance legislation. Many well-attended meetings were held, and out of about 60 members of the profession from 30 to 40 were generally present, which was creditable considering the great distances some of them had to travel in a county where railways are scarce. They discussed not merely the financial and professional aspects of the proposals, but especially whether its effects would be good or bad for the public. In regard to the financial question, great difference of opinion prevailed. Some practitioners said that it would pay very well to have the extension of contract practice, and others thought that there would be serious loss on the whole, but at least 90 per cent. of the profession were convinced that the proposed law would degrade medical science, and consequently be to the public detriment. With the one or two exceptions of practitioners entirely dependent on club patients, the money side of the question did not disturb these Essex doctors. Several among them expressed their readiness to lose all their club patients, though these in more than one case exceeded 1000 in number. Nevertheless, they were willing to put up with a considerable financial loss rather than lose their independence by observing the Act. Thus, when the Representative Meeting of the British Medical Association met in London in December, 1912, the Colchester delegate went up with full instructions to vote against working the Act. Most of his co-delegates from all parts of the country had similar instructions. Speaking to me, the Colchester representative described the extraordinary enthusiasm which prevailed when the Representative Body voted that the Act was derogatory to the profession. He returned to Colchester profoundly impressed that the Act was shattered and would never come into force.

How Colchester Capitulated.

There was, however, an early awakening from such illusions. Almost immediately after the representative meeting, and in spite of its brave decision, it was found that many were shaky in their alliance. Medical men in outlying country districts were reported as desirous of going on the panel, and rumour, assisted by advertisement, reported huge rushes of medical men on to the panels in various parts of the country. These newspaper reports greatly perturbed the profession. The country doctors who were in the strongest position, for they had no cause to fear that doctors would be imported to take their place, were to some extent won over by the permission, the very necessary permission, to dispense, so that they would receive the entire sum set aside for medical benefit. But in the countryside, if importations were not feared, yet every local practitioner was bound to be influenced by what his neighbours might do. All the men in the Colchester area protested their willingness to hold out, if no one in the neighbouring areas gave way. The rural doctors were the first to give way, and this because of the overlapping of practices established in districts outside the Colchester area. It was, therefore, from the circumference to the centre that defeat spread. Some country doctors were absolutely consistent in their opposition, while the town doctors stood out till well into January, 1913. Early in that month a meeting of the town practitioners was held, and here again it was decided unanimously not to go on the panel. Though this decision would mean the absolute ruin of one or two practitioners, still all were quite firm in the determination to resist. Then came the celebrated message, which has become an historical event, received by Dr. Leigh Day from Mr. Worthington Evans, M.P. The latter telephoned, inquiring what the Colchester doctors were going to do, and received the prompt reply that they were going to fight. Mr. Worthington Evans thereupon expressed his doubts as to the wisdom of this course, and explained that the Government was going to make an example of certain towns of moderate size. The result was that Mr. Worthington Evans came down to Colchester on the next day to tell what he knew about the proposed Government action. Another meeting of practitioners was held which sat for three hours. It was then seen that resistance was useless, but in revoking their former decision it was urged that the best way to mitigate the evils of the Act was for everyone to go on to the panel. As this resolution was adopted on a Saturday afternoon motor cars were sent round all Sunday to warn those who had not been able to attend the meeting. The profession proved as united in accepting the Act as they had been in resisting the Act, and this is in itself a matter of congratulation for them. They yielded when they could hardly do otherwise, and they so yielded as to leave little material for internal recrimination.

The Financial Results of the Act.

There can be no doubt that the fight has done an enormous amount of good in bringing the members of the profession together. Never before had they experienced such trying times, they were not all of one mind even when loyalty made them espouse a common cause, and to-day no bitterness of feeling or resentment prevails. It must be confessed that the financial results, by creating an agreeable surprise to many of them, have conduced to harmony. Only two doctors in the town and one in the outside or rural part for the Colchester insurance area have not gone on the panel. The probability is that they have experienced some loss, as some of their patients have been compelled to insure under the Act. The great majority of practitioners are satisfied with the financial results. Those who had many club patients have not found that these patients profited by the freedom of choice to leave their old club doctors. The club doctors have not lost patients, but are much better paid by these patients and have got others who were not members of clubs. Therefore their financial position has improved.

I will take a firm of three doctors as a concrete example of financial results. They had not many club patients. One of the three partners had no club patients and no contract work whatsoever. He now has a list of 450 insured patients, and about 200 of these were formerly private patients. His partners did have club patients, about 300 to 400, and they now have instead some 600 to 700 insured persons each, but many of these used to pay fees for advice. Altogether the three partners received under the Act for the first year £700. This is an increase of £350 over their former takings from the same sources, but 1912 was, as it happened, a bad year and 1913 an exceptionally good one, so they do not reckon on a permanent average increase of more than about £100. If this is not much when divided by three partners, nevertheless they can safely say that not only have they lost nothing, but they can rely apparently on at least a small improvement. This is a typical example of the all-round experience. The feeling is that it does pay to have a list of insured persons, and everybody at Colchester is satisfied with the financial aspect of the Act; but many practitioners still hate the sort of work they have to do, though some admit that in this direction the working of the Act is not as bad as they had anticipated.

The Medical Committee and the Commissioners.

The Act, it seems, if I may trust some of the opinions expressed here, is good enough, but the administration is very bad. One of my informants, speaking as a practitioner, expressed himself as quite satisfied; but as chairman of the Local Medical Service Subcommittee and as chairman of the Panel Committee he was very dissatisfied. The work they had to do after communication with the Commissioners was unsatisfactory through no fault of theirs, he considered. The replies they received came too late, and had on occasion been contradictory—complaints which have been made to me elsewhere. Colchester claims that it was the first town in Essex to form a Local Medical Committee. Very soon after its formation a scheme for the re-election was, in keeping with the requirements, duly drawn up. This was forwarded to the Commissioners 15 months ago, who did not reply.

As there are only three practitioners in the Colchester area who are not on the panel, it will be seen that practically the election of the Medical Committee and the Panel Committee depends on the vote of the same persons. Local opinion was opposed to duplication, and wanted the elections for the two committees to take place at the same time, resulting probably in the return of the same candidates for the two committees and the assimilation of their work. The Medical Committee of course was elected and at work long before there was any question of a Panel Committee, and the Medical Committee did its work so well that medical benefit was working better in Essex than in most places, yet there seemed to be an antagonism on the part of the Commissioners towards the Medical Committee. So much so that though, as a matter of form, questions were sent by this committee to the Commissioners, the committee had given up expecting favourable replies, said my informant. Moreover, it has not been admitted that the members of the Medical Committee have any right to claim their railway expenses. These amounted to £40, which if divided amongst the 484 practitioners of the Essex panels would not amount to 2*s.* each. Laymen who are on the Essex Insurance Committee are paid their expenses; medical men who are elected members of the Essex Medical Committee, formed in accordance with the Act, have to pay all their expenses out of their own pockets. Yet both are administrative expenses.

Administrative Difficulties.

Then there is a financial difficulty at Colchester, which may have arisen elsewhere, but which I have not before come across that I remember. The secretary of the Medical Committee is a medical practitioner and a member of that committee. Out of a voluntary levy he was paid a certain sum a year for his work as secretary. Now, and as both committees consist of the same persons, he is secretary of the Panel Committee. The Panel Committee, being an administrative committee, has a right to claim payment for its expenses out of the insurance funds. Thus it was hoped that the ½*d.* to be taken from the floating sixpence would go to pay the secretary's salary. But the Commissioners have replied that no member of a committee is to receive a salary. The secretary must retire from the committee if he is to be the paid secretary of the committee. He would therefore not be able to bring forward urgency motions or take any initiative in the work which he has been managing since the Act came into force. There is far too much work for any panel doctor to act as secretary for the Panel Committee unless he is remunerated. In a word, the Act is no longer attacked or criticised; it is the administration, especially that which is carried out centrally by the Commissioners, which is the object of most of the fault-finding.

(To be continued.)

THE INTERNATIONAL SURGICAL ASSOCIATION.

(FROM OUR OWN CORRESPONDENT.)

(Concluded from p. 1345.)

Gastric and Duodenal Ulcers.

A DISCUSSION on the production and treatment of gastric and duodenal ulcers was opened on Tuesday, April 14th, by Dr. A. LAMBOTTE (Brussels), who said that it had been clearly established that pyloric exclusion constituted an important supplementary procedure to gastro-enterostomy. Of all the methods devised to effect this exclusion the simplest was by ligature of the pylorus. He described the procedure and said that its great advantage was its extreme simplicity, only taking a few seconds. As for peptic ulcers, Dr. Lambotte believed that it was necessary to seek their origin in the operative technique which had been followed rather than in the pathological disposition of the patient. In addition to those whose remarks are summarised, Dr. Block (Copenhagen), Dr. Kümmel (Hamburg), Dr. Ullmann (Vienna), Dr. Manniger (Budapest), Dr. Zahradincky and Dr. Keynski (Russia) took part in a most valuable discussion.

Dr. Charles L. Gibson (New York), who spoke in French, cited statistics collected by Dr. D. R. Turnure from the Hudson Street, Roosevelt, and St. Luke's Hospitals, regarding the outcome of operations on patients suffering from gastric and duodenal ulcers during the past 18 months.

Dr. Sonnenburg (Berlin), referring to the diagnosis of gastric or duodenal ulcer, said that this was by no means an easy matter. The speaker commenting on the value of radioscopy said that, according to Max Cohn, contraction and too rapid emptying of the stomach were in no sense pathognomonic but only accompanying symptoms of gastric and duodenal ulcer, but that retention of bismuth in the duodenum was significant. Abnormal gas formation in the duodenum was of special import, especially gas bubbles in the first portion of the duodenum. In his personal experience the bismuth test had not been absolutely reliable. The majority of medical men in Berlin agreed that the diagnosis of duodenal ulcer remained a probable rather than an absolute diagnosis. With regard to the relative frequency of gastic and duodenal ulcer their experience was at variance with that of American surgeons. In his series of cases there were 13 duodenal and 67 gastric ulcers. The information given by Moynihan and American surgeons had assisted him in making a diagnosis in many instances.

Dr. Brüning (Giessen) said that the symptom-complex described by Moynihan occurred in many cases of ulcer of the stomach, but was absent in others. There was no way in which one could be absolutely certain as to the situation of the ulcer. The von Eiselsberg Ausschaltung method of operation was undoubtedly the best.

Dr. Arthur D. Bevan (professor of surgery at the University of Chicago) referred to the experiments of his colleague, Dr. Edward C. Rosenow, with regard to the origin of gastric and duodenal ulcers and the transmutation of certain bacteria under certain conditions. These experiments in producing artificial ulcers in animals were based upon an earlier series of experiments. Dr. Rosenow had taken certain strains of bacteria and injected them intravenously into animals and produced endocarditis. He then took the same bacteria and cultivated them in a different medium, and the strain so produced, when injected into animals intravenously, invariably brought about inflammatory infectious lesions of the joints. The conclusion was that each strain possessed a selective action for some distinctive type of tissue. Proceeding on this principle, he isolated bacteria from the exudate of gastric and duodenal ulcers, cultivated them in other media, and by injecting them intravenously into animals set up gastric and duodenal ulcers. Dr. Bevan remarked that the result of Dr. Rosenow's investigations were extremely suggestive.

Dr. John B. Murphy (Chicago) corroborated Dr. Bevan's account of Dr. Rosenow's investigations. Rosenow, he said, appeared to have shown that a single strain of streptococcus will by change of environment alter its character and will, when injected into animals under suitable conditions, bring about endocarditis, inflammatory infectious lesions of the joints, and acute gastric and duodenal ulcers and probably other diseases. Dr. Murphy gave it as his opinion that gastric ulcers were caused by infection in other parts of the body, and pointed out that such ulcers were more prevalent at that period of the year when infections of the respiratory tract were rife. Commenting upon the button which goes by his name, Dr. Murphy said that he still used it; not, however, the round button, but an oblong button which he introduced ten years ago.

Dr. Howard Lilienthal (New York) said that when conditions were favourable he excised ulcer-bearing areas at once. When, however, there was a large indurated mass near the pylorus a large operation was necessary to remove it. In such a case he first did a gastro-enterostomy near the pylorus and close to the median line, and afterwards, when the patient had recovered strength, he performed a pylorectomy. In ulcer of the stomach with indurated deposits he therefore performed a two-stage operation.

Dr. A. Gerster (New York) drew attention to the danger of infection resulting from the use of sutures, and emphasised the fact that medical treatment of gastric and duodenal ulcers was as important as surgical measures.

Dr. Albert Ochsner (Chicago) said that gastric and duodenal ulcers were due in the large majority of cases to the habitual abuse of normal feeding which gave rise to the long-continued irritation of hyperacidity. Dietetic and medical treatment would often effect a cure.

Dr. Rodman (Philadelphia) considered that while patients suffering from gastric or duodenal ulcers made a recovery after operation, in many instances they were not cured. Even more radical treatment was indicated. It was difficult to diagnose correctly between ulcer and cancer of the stomach. He thought the reason why medical men did not perform pylorectomy or excision of ulcers of the gastro-intestinal tract more frequently was the exaggerated idea of the gravity of these operations. From statistics he had collected he was more than ever convinced that the operations were less dangerous by far than was generally supposed. He agreed with Lilienthal that if a two-stage operation were more commonly practised the mortality could be considerably decreased. His experience had taught him that ulcers at the pylorus most often became malignant, but that such an occurrence in other parts of the stomach was rare. On the whole, he considered that pylorectomy was the most effective operation.

Dr. William J. Mayo (Rochester, Minn.) preferred a one-stage operation. Speaking of Dr. Rosenow's findings, he said that investigations in the same direction were going on at St. Mary's Hospital, Rochester, but he wished to point out that although Rosenow had produced acute ulcers in animals he had not produced chronic ulcers. Acute gastric and duodenal ulcers seldom became chronic, and as carcinoma never developed at the bases it must be grafted on.

On Wednesday, April 15th, a discussion was opened on

Grafts and Transplantation.

The plastic art of surgery is not so highly developed in America as in France and in some other parts of Europe, and to many present the papers read were a revelation. Especially was the audience impressed by the paper and illustrations of Dr. Lexer (Jena), who is well known as a pioneer in this branch of surgery. Dr. Lexer told of successful joint transplantations done by him, and pointed out that substitution of half a joint can be as easily accomplished as that of an entire joint, and said that the possibility of organic incorporation of a transplanted joint taken freshly from man had been proved. He held that his mission consisted in establishing the practical value of grafting on the basis of his own personal work and experience. His conclusions were as follows:—

> The value of the various tissues employed for grafting was differently appreciated by practitioners and by pathologists. An excellent clinical result might be obtained not only if the graft, in taking, preserved its entire structure, but also if it disappeared slowly giving place to substitution tissues or was completely surrounded by adhesions. The circumstances of clinical failures must be taken into account. The graft might be expelled by a violent reaction or disappear in a slowly progressive suppuration, or small blood-clots might prevent the nourishment of the transplanted part from becoming established. The conditions necessary for obtaining a good implantation were vitality, nutrition, powers of acclimatisation, and the condition of the wound on which the implantation was made. Scrupulous asepsis must be observed. Dr. Lexer pointed out as new the simple transplantation of the skin without epidermis, and considered in detail the clinical results of the transplantations of mucous membranes, muscular, nerve, and vascular tissues, tendons, aponeurosis, periosteum, peritoneum, bone, cartilage, and joints.

Dr. H. Morestin (Paris) began by showing that graftings and transplantations of tissues had considerably enlarged the limits of reparatory surgery. For the proof of this it sufficed to glance over the actual treatment of the principal injuries and deformities for which plastic operations were employed, to note the changes made in the results by cutaneous, epidermic, cartilaginous, and fatty grafts. Free cutaneous grafting succeeded fairly well under determined conditions—a small fragment taken from a soft thin skin and deprived of its pannicule applied on a living surface strictly aseptic. But these indications remained very limited, especially in reparatory surgery of the face, on account of the trophic disturbances of the graft and the yellowish or whitish colouration which it preserved indefinitely. The Italian method of cutaneous transplantation at two distinct periods, notwithstanding the difficulties attendant, was the most satisfactory. But he thought that it must remain an exceptional method even for rhinoplasty and blepharoplasty, operations for which it was specially recommended. Its triumph was the reconstitution of the lobule and the septum of the nose by the skin from the palmar surface of the hand. Dermo-epidermic graftings had innumerable indications in the treatment of superficial wounds, and especially of those whose extent prevented true methods of autoplasty, such as in great loss of substance following on burns, traumatism, or removal of tumours. These grafts alone secured the healing of wounds resulting from the tearing off or complete destruction of the scalp. They were particularly recommended in cutaneous malignant disease in old people, but in lupus and deformities caused by scars they constituted a last resource. Grafting of hairy parts was attainable either by free transplantation or by means of a fragment, this last method being much more preferable. By this means the eyebrow and even the moustache might be restored. The transplantations of cartilage constituted one of the most remarkable innovations in reparatory surgery. It was thanks to this that the question of total rhinoplasty had been solved. For centuries the difficulty of establishing a framework had been the stumbling-block. This difficulty overcome, all became attainable. For, in spite of various attempts, nothing of any worth could be attained when no use could be made of the cartilaginous prothesis. From this moment truly dated the rhinoplasty worthy of the name. Cartilage showed great power of absorption, and preserved its life during an indefinite period. This unique stability and its adaptability for modelling rendered it very valuable for the construction of nasal frameworks. Besides total or subtotal rhinoplasty, and the correction of nasal malformations, other restorations might doubtless benefit by cartilaginous grafting. In incorporating fragments of cartilage with cutaneous pieces surgeons were able, for instance, under given conditions to fill up certain gaps in the jaws and in the soft parts surrounding which hitherto they had no means of doing. Adipose graftings were excellent for filling up bony hollows, for effacing the depressions of soft parts, and therefore rendered great service in the repairing of cranial gaps and facial deformities. Fatty tissue with few blood-vessels was easily transplanted, provided that it was placed in a rigorously aseptic surrounding. After a more or less short struggle it succumbed, but it was replaced progressively by tissues of new formation to which it served as a sort of protection. Thus its rôle was transitory, which did not prevent its result from being stable. Adipose grafting was a very valuable acquisition to æsthetic and reparatory surgery.

Dr. JOHN B. MURPHY (Chicago) in the course of his remarks said that for the restoration of a joint it was necessary that there should not only be non-union, but a sliding joint and functional restoration. In the reconstruction of the knee and hip it was necessary in addition that the joint should be able to support pressure. These requirements were met by reconstructing the bones on the plan of their original conformation by means of transplants and by the interposition of fascia covered by fat. He had succeeded in reconstructing an ankylosed knee by the detached fat fascia, but he had not done this in the case of the hip.

Professor A. DEPAGE communicated the results of some experiments made by his assistant, Dr. Danis, leading to the restoration of the biliary canal in dogs by means of a segment of the jugular vein.

Grafting of Blood-vessels.

Dr. E. VILLARD (Lyons) read a paper on this subject and said that there existed two large categories of vascular graftings—extemporaneous grafting and grafting of preserved vessels. Arterial graftings were distinguished from venous graftings by the nature of the graft. A grafting was auto-, homo-, or heteroplastic according as the graft was taken from the subject under treatment himself, from a subject of the same sort, or from a subject of a different sort. In extemporaneous grafting arterial autoplastic grafting healed without modification; the segment grafted acquired new life in its new surroundings with the histological structure that characterised it. Arterial homoplastic grafting gave macroscopically good results, but was not so satisfactory. Arterial heteroplastic grafting was possible, but it appeared that the graft served only as a protection to a process of reparation on the part of the animal undergoing the grafting. Venous grafting was difficult to effect. In the grafting of preserved vessels some vascular fragments might be grafted with success, due regard being had to asepsis and temperature. Surgery might benefit by the use of vascular grafting in three cases: (1) in the course of vascular traumatism; (2) in the extirpation of a tumour adherent to the large vessels; and (3) in the cure of aneurysms.

Dr. E. ULLMANN (Vienna) said that the hopes raised 15 years ago on the future of transplantations of tissues and organs had only been partially realised. Heteroplasty seemed to meet with anaphylaxis as the principal obstacle, whilst homoplasty encountered the biochemical properties of the individual. Autoplastic transplantations alone gave good results, while heteroplastic transplantations, with the exception of bony tissue, always gave bad results. The results of homoplastic transplantations were variable; given an identical quantity of sanguineous serum from the cellular protoplasm of two subjects in the same condition, homoplasty might probably give as satisfactory results as autoplasty. More research was wanted in this direction.

Dr. ALEXIS CARREL said that during the last few years it had been definitely established that autoplastic transplantations of organs were practically always successful; that homoplastic transplantations, although the immediate results might be excellent, were nearly always ultimately unsuccessful, and that heteroplastic transplantations were always unsuccessful. Although the technical part of the problem of the transplantation of organs had been completely solved long ago, this operation could not yet be applied to human surgery. Homoplastic grafts alone would be of use; but before being practicable homoplastic transplantations must be rendered as safe as autoplastic transplantations. The present aspect of the problem was to find out the causes of the reaction of an organism against a new organ and to discover by what means this reaction could be prevented and the organ made to become adapted to its new owner. Dr. Carrel described a series of experiments in this direction which had been made recently by James B. Murphy of the Rockefeller Institute, and said that a very important point had been gained by the discovery that the power of the organism to eliminate foreign tissues was due to organs such as the spleen or bone marrow and that when the function of these organs was less active a foreign substance could develop rapidly. It was not possible to foresee whether or not the present experiments of Dr. Murphy would lead directly to the practical solution of any of the problems, but it was certain that he had contributed very important work.

Conclusion of the Meeting.

The meeting, which was a scientific and social success, terminated on the afternoon of April 16th with the election of Dr. W. W. Keen, of Philadelphia, as the next president. The other officers of the society were re-elected, with the exception of the secretary for the next meeting. The election of this officer will be made later. Paris was chosen as the place of meeting in 1917.

During the meeting clinics were held at the principal hospitals. Among the entertainments and functions provided were a dinner given on April 13th by the American Surgical Association to the members of the International Society of Surgery and the ladies accompanying them. On April 14th a luncheon was given to the ladies by Mrs. W. J. Mayo at the Hotel Biltmore. On the same day a matinée performance of *Peter Pan* was given for the ladies, and in the evening a special performance was given at the Metropolitan Opera House, at the instance of the American Surgical Association, to all the members and the ladies accompanying them. On April 15th the President's reception was held.

Dr. Mayer, in the course of reading the general secretary's report, pointed out that 114 new members proposed by the National Committees had been elected by the International Committee—namely, six Germans, one Austrian, one Belgian, two Canadians, 74 Americans, 14 Danish, one English, two Italians, one Norwegian, four Dutch, one Roumanian, four Russians, one Swiss, and two Hungarian candidates.

A very excellent and full display of surgical instruments was given in rooms near the hall in which the meetings were held. A feature of the exhibition was supplied by Messrs. Allen and Hanburys (London), who sent specimens of the instruments designed and used by Sir Arbuthnot Lane in his fracture-plating operations.

To the courtesy, tact, and ability of the two secretaries, Professor L. Mayer, of Brussels, and Dr. J. P. Hoguet, of New York, the smoothness of all the arrangements was mainly due, and your representative wishes to express his personal thanks to both of these gentlemen for their ready and valuable help.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

SCOTLAND.

Annual Report of Medical Officer to the Scottish Education Department.

Dr. Lewis D. Cruickshank, in his report for the year ending July 31st, 1913, emphasises the fact that medical treatment of school children is inefficient, though the organisation for medical inspection is satisfactory. The reports of the medical inspectors show that there is a great amount of malnutrition among Scottish children. These reports make it clear that the malnutrition is in most cases the result not of deliberate neglect, but of ignorance of the parents as to the nature and amount of foodstuffs most suitable for children, and the importance of adequate sleep and fresh air. Therefore, the more nearly medical inspection touches the home the greater will be the measure of success. The medical officer for the mainland division of Inverness reports that the substitution of tea and bread for porridge and milk has not appreciably invaded his district, to which he attributes the comparative absence of malnutrition among the school children, but the medical officer for Sutherland finds a considerable percentage of cases of malnutrition which he attributes to the tea and bread habit. A careful study of the figures makes it clear that there must be a considerable difference in the standards adopted by the various inspectors. In Aberdeen the number that suffered from "poor nutrition" was 19·4 per cent.; in the Glasgow board schools "bad nutrition" amounted to 4·13 per cent., and in Govan to 1·5 per cent. In Greenock the cases returned as "below average" amounted to 21 per cent. In the counties the differences are even more marked. A great improvement is reported in the conditions of personal cleanliness, though some larger school boards systematically neglect their legal powers in regard to the parents of verminous children. There would appear to be about 10 per cent. of school children suffering from defects of sight requiring treatment. The problem of conservation of sight is therefore a very pressing one. The majority of medical officers are emphatic that dental treatment is one of the most pressing problems. The medical officer for the Govan board states that out of 10,915 children examined, at least 9676 had one or more teeth requiring attention. About 1489 new cases of tuberculosis were discovered during the year under review. Approximately 576 were cases of pulmonary disease, 204 diseases of bones and joints, 333 of gland disease, and 376 unclassified. There are in all 41 separate schemes of medical inspection in Scotland. Of these, 30 are schemes prepared and administered by the County Secondary Education Committees, and 11 are schemes administered by burgh school boards. The number of school medical officers is 110, and the total number of whole-time nurses employed is 52. The total number of children examined during the year was 350,831, out of a total average number of scholars of 809,995.

Kincardineshire Medical Officer's Annual Report.

The death-rate of children under 1 year, as stated in the twenty-third annual report of the medical officer of Kincardineshire, is 102 for every 1000 children. Last year the death-rate was 77 per 1000. For 1913 the zymotic death-rate was 1·061 per 1000. Deaths from all tuberculous diseases caused 7 per cent. of the total deaths. Deaths from malignant disease were 19, equal to a death-rate of 0·916 per 1000. In 1912 there were 23 deaths, equal to 1·1 per 1000. It is noted in the report that, as in former years, almost half the cases of consumption were notified from the St. Cyrus district, and that two out of every three deaths from consumption took place within that district.

Aberdeenshire Panel Practitioners.

A meeting of Aberdeenshire panel practitioners was held on May 15th, when the question of the 20 per cent. deduction from the quarterly cheques of the practitioners, and the position of chemists with regard to the drug fund, were discussed. The meeting was very largely attended. The question of Postcard 547, issued by the Insurance Commissioners, first came up, and it was unanimously agreed that no notice be taken of the postcards, as they were calculated to create strife between the chemists and the panel practitioners. In the course of the discussion it was pointed out that the wording of the postcards was so ambiguous that it was impossible for an answer to be given definite enough to be of any value. The drug fund was discussed and the opinion of the meeting was that the fund for Scotland should be pooled, and that an auditor paid by the Insurance Committee should be appointed to check the chemists' accounts. It was resolved, with regard to Circular 545, to express no opinion upon the purely commercial matter of drug prices; but the meeting found that there was no reason to doubt the statements made by the chemists with regard to the alleged inadequate remuneration which they were receiving for dispensing where skilled compounding was required, and the meeting expressed its sympathy with them in their demand for better terms. With regard to the 20 per cent. reduction from the practitioners' cheques, it was decided that legal opinion be taken as to the legality of the procedure. It was also resolved that the County Panel

Committee should combine with the Burgh Panel Committee in any action taken to protect practitioners' interests, and that meantime the facts of the case be laid before the Scottish Committee of the British Medical Association to secure an immediate protest being made to the Commissioners. The meeting further resolved that, as the present unsatisfactory state of affairs was largely due to the carelessness and inefficiency of Approved Societies over index slips, the Commissioners be requested to take immediate steps to deal with the societies concerned.

May 19th.

IRELAND.

The Public and the National Insurance Act.

THERE are signs that public hostility toward the working of the sickness benefit of the National Insurance Act is gradually growing. Members of Approved Societies are beginning to learn that their only hope of obtaining fair treatment is by reliance being placed on the certificates of their own medical attendants. From all parts of the country the complaint comes that benefit is refused to members unfit to work by reason of sickness. Most of these people present certificates of incapacity signed by their own medical attendants, but these are cast aside in favour of the opinion of the "medical adviser." In many cases the sick member, on refusal of benefit, has to seek help from the rates, either in the form of out-door relief or of treatment in the workhouse infirmary. The County Westmeath board of the Ancient Order of Hibernians—the largest Approved Society in Ireland—by a unanimous resolution last week called attention to the grave injustice suffered by insured members under the present system of certification by "medical advisers."

The Local Government Board and the Insurance Commissioners.

One of the drawbacks of Irish administration is that where the activities of various Government departments overlap there seems to be little attempt at harmonious action. In matters affecting the public health we have had unfortunate overlapping between the Local Government Board and the Department of Agriculture. Only a few years ago the manager of a model farm of the department was prosecuted because the sanitary condition of the farm-yard did not satisfy the regulations approved by the Local Government Board. Since the passing of the National Insurance Act there has been the additional confusion caused by the overlapping between the functions of the Insurance Commissioners and those of the Local Government Board. No attempt seems to have been made to arrive at any agreement between these two bodies on points of public policy. Both are concerned in advising and controlling the tuberculosis campaign, and it not infrequently happens that the Local Government Board gives one kind of advice and the Insurance Commissioners the opposite.

The late Dr. Henry O'Neill, J.P.

The city of Belfast, the medical profession, and the cause of public health are all the poorer by e death of Dr. H. O'Neill in his 61st year, which curred at his country residence near Belfast on May 16th, after an illness that began as pneumonia on last Christmas Eve. From this attack he recovered, so that for a time he resumed work, but a few months ago he was obliged to take to his bed with cardiac complications, and was never out again. Dr. O'Neill, who claimed to be a lineal descendant of the great Hugh O'Neill of Dungannon, was born at Crossnacreevy, co. Down. In 1868, while still young, he entered the establishment of a well-known firm of chemists in Belfast, but his ambition was to become a doctor, and he studied at Queen's College, Belfast, and in 1877 graduated M.D. and M.Ch. of the Royal University of Ireland, obtaining the M.A.O. in 1900. In the year 1877 he became a house surgeon at the old Belfast Royal Hospital. Two years later he became assistant surgeon, in 1882 full surgeon, in 1884 pathologist, and in 1900, when he retired, consulting surgeon to the Belfast Royal Hospital (now the Royal Victoria Hospital). Beginning practice in 1879 in Belfast he rose rapidly, and for many years had an immense working class *clientèle*, his consulting rooms in the afternoon and evening being crowded. Turning his attention to public health, he established the *Belfast Health Journal*, and on this platform he entered the city corporation, where he spent over 20 years of public life, at the time of his death being chairman of the market committee. In 1905 he was High-Sheriff of the city. Dr. O'Neill was also a barrister-at-law of both the Irish and English bars. He was curator of the Museum of Sanitary Science at Queen's College, Belfast, and an ex-president of the Ulster Medical Society and of the North of Ireland Branch of the British Medical Association. The health schemes, for which he will always be remembered, will be the inspection of meat, the building of the new Belfast city abattoir at a cost of £52,000, as well as the alterations and improvements which he had carried out at the Belfast city court-house, by which the scandalous sanitary condition of that place was put right and proper accommodation was provided for the Bar, jurors, litigants, and witnesses. Dr. O'Neill was a many-sided man whose memory will long be cherished in Belfast for his health reforms, his private benevolences, his medical skill and his cheery optimism; but to his patients he will always be remembered as one of the kindliest of men.

Derry Water-supply.

The Irish Local Government Board have suddenly reversed their previous decision,[1] and have now written that they have decided, with some misgivings, to grant a provisional order sanctioning an auxiliary water-supply to Derry. This complete change of front on the part of the Local Government Board has been due to the growing volume of protest raised by their previous action, and especially to a resolution passed unanimously by the Derry Chamber of Commerce requesting them to reconsider their decision, and pointing out that any shortage in the water-supply would be disastrous to the trade of the city. The Chamber of Commerce at the same time urged upon the corporation "the necessity of proceeding without avoidable delay with a larger scheme for a full and satisfactory water-supply." It is a great pity that the Local Government Board did not more thoroughly take every aspect of the question into consideration before committing themselves so definitely to a decision which is no sooner given than it is reversed.

May 19th.

[1] THE LANCET, May 16th, 1914, p. 1422.

PARIS.

Antityphoid Vaccination of Hospital Staffs.

Two years ago the Assistance Publique of Paris decided that all male and female nurses and attendants of the Paris hospitals must undergo antityphoid vaccination with either the Chantemesse or the Vincent vaccine now in use in France. This measure was especially necessary since the personnel, including medical students employed in the hospitals, had yearly furnished some deaths from typhoid contracted while caring for typhoid patients. Up to the present this regulation has worked without friction, but last week the hospital employees held a meeting at which they refused henceforth to submit to such vaccinations. They alleged that two nurses had died, one at the Beaujon, the other at the Necker, after it; that many more had been rendered seriously ill; and finally that one, having been wounded by broken glass during the incubation period of the vaccination, had sustained such serious accidents that it would be necessary to amputate her arm. The syndicate of nurses contended that under these circumstances it would be better to suspend the inoculations, as had already been done in the army, for two months. This event has caused considerable public excitement. M. Chantemesse and M. Vincent have asserted that their respective vaccines, which have now been used in hundreds of thousands of cases without any accident, could not be held responsible. It is true that the Vincent vaccine, prepared by either sterilisation of cultures, necessitates four injections at eight days' intervals, and that during this period, which is characterised by a negative phase, the subject is in a state of great receptivity. It must be added also that after the inoculation the subject should be allowed to remain strictly at rest, and should avoid overfeeding, which can hardly be fully carried out with the personnel, male and female, of the hospitals, devoted as they are to their work and regardless of danger. The director of the Assistance Publique has replied to the allegations by stating that 1055 inoculations had been made up to date without any accident occurring, and that only 40 employees had broken the series of four injections considered necessary for immunisation. It was in these circumstances that one of the nurses succumbed. The other had not been submitted to preventive vaccination, but having contracted typhoid had been treated during the course of the disease with vaccine, but without success, as is frequently the case. As to the nurse who was wounded in the arm, the arm had not been amputated, but there had been a phlegmon consecutive to a wound, but entirely without relation to the antityphoid inoculation, which had been all over several days before. The director added that the vaccination is not enforced in the case of those already employed, but only with the newly appointed. At a later meeting the syndicate of hospital employees passed a resolution disclaiming any hostility to the vaccination, but demanding that precautions should be taken henceforth to ensure that the necessary rest is taken after the vaccination, and especially that a selection of cases is made before vaccinating, because it was alleged that very many were in a state of bad health, and a third of them were tuberculous. The important question is thus arising as to the right of the executive of any administrative body to impose vaccination of any kind upon its personnel. Particularly since the new Workmen's Compensation Act, which imposes fresh pecuniary liabilities on employers, it is to their interest to accept only those who by vaccination present the smallest chance of developing occupational diseases. Amongst the excavators on the Metro to-day antitetanic vaccination is required, but no law demands it, and it might very well happen that a workman should bring an action against his employers for having imposed it. It will be interesting to know what the law will have to say on this novel question.

The Feeding of Infants.

According to the views expressed by M. Wallich and M. Denesse in a paper at the Société de Médecine Publique et de Génie Sanitaire as to the causes that compel poor mothers to desist from suckling their children, 70 per cent. are driven thereto by the necessity of continuing their work to obtain means of subsistence. Of the children thus put out to nurse the mortality is 50 per cent., and this produces one of the most serious causes of the depopulation of the great towns. Although masked by the continual immigration, this depopulation becomes evident each year that the census is taken. Undertakings have, however, been established in large numbers, both by the authorities and by private initiative, to remedy this state of things. In many factories crèches have been established where mothers can leave their children while they are at work. But such are as yet too few in number, and apply only to the women workers in factories and not to women clerks, shop assistants, and the like. The Assistance aux Mères Nourrices, by furnishing them with work that can be done at home, is of service under limited conditions, but it only results in a miserable wage. The society was driven to the conclusion that in this matter lay one of the most serious social problems of the day. An inquiry has been recently undertaken by Dr. Variot into the matter. It showed that bottle-feeding was giving, in regard to the development of the infant in weight and health, results almost equal at the end of a year to those obtained by breast-feeding; but it was mixed feeding—that is to say, partly the mother's breast and partly the bottle—which in the working class gave far the best results, doubtless because of the inferior quality of the mother's milk in these cases.

May 18th.

UNITED STATES OF AMERICA.

Annual Convention of the American Surgical Association.

THE annual meeting of the American Surgical Association was held at the Hotel Astor, New York, from April 9th to 12th. The attendance was large, among those present being 40 or more surgeons from Europe who had come for the meeting of the International Surgical Association, whose meetings have been reported in THE LANCET of May 2nd (p. 1269) and subsequently. A feature of the meeting was the papers and discussion on cancer and its treatment. Dr. W. J. Mayo, of Rochester, Minn., made cancer the subject for his presidential address, and among other points emphasised the fact that the radiologist had been able in 100 consecutive cases of cancer of the stomach to make a definite diagnosis in 87 per cent. The best that had been accomplished by other means was 67 per cent. Dr. Mayo was of the opinion that this method of diagnosing malignant disease of the stomach was entitled to the first place, and he would be inclined to place it second in value in diagnosing obstructions of the duodenum. He thought that food was to blame for the prevalence of precancerous conditions in the gastric regions among civilised peoples. The quantity eaten in civilised communities brought about chronic gastric irritation which in some instances resulted in cancer.

Radium in the Treatment of Malignant Growths.

Dr. Richard Sparmann, of Vienna, a member of the clinic of Dr. Anton von Eiselsberg, read a paper on the treatment of malignant growths by means of radium. Dr. Sparmann said that 42 cases of malignant tumour had been treated by radium at the Eiselsberg clinic; of this number 17 had died, 5 from causes other than tumours; 6 had been benefited; 5 cases had shown no effects; while 14 cases had been positively aggravated. According to Dr. Sparmann the experiments in Vienna had demonstrated the fact that radium was effective only in superficial cases of malignant tumour, and even then was effective in no marked degree. Radium had actually made worse many bad tumours by destroying healthy tissue around them, so that there was nothing left to check the spread of the tumour. There had been no specific change in tissue effected by the use of radium, and it did not appear that it would ever replace operation in the treatment of cancer. The hopes that had been placed in radium had not been realised. Dr. Robert Abbe, of New York, said that in his experience radium had exerted marked beneficial action on certain forms of malignant growths, and while he would say nothing about radium curing cancer, it did, he thought, act specifically, and from this point of view it should be studied. The majority of the audience, however, appeared to agree with the conclusions of Dr. Sparmann. The statement made by Dr. Mayo that early diagnosis and prompt surgical treatment were the sole effective measures at present known for cancer met with the approval of most of those present.

Clinics at the Polyclinic Hospital and Medical School, New York.

During the week in which the International Society of Surgery met in New York a series of clinics and lectures were held at the Polyclinic Hospital and Medical School. The first of these was on April 14th on internal photography as an aid to diagnosis, by Dr. Alfred C. Jordan, of London. On April 15th Dr. Eugene Hertoghe, of Antwerp, gave a lecture and demonstration on hypothyroidism. On April 16th Dr. Benjamin Merrill Rickette, of Cincinnati, Ohio, gave a lecture and demonstration on the surgery of the heart and lungs. On April 17th Dr. John Wyeth discussed the treatment of burns, Dr. John A. Bodine operated for the radical cure of hernia, Dr. Alexander Lyle demonstrated the treatment of fractures, and Dr. William Seaman Bainbridge, professor of surgery at the Polyclinic Hospital, discussed cancer and its treatment, and exhibited patients on whom he had operated for this disease.

Complimentary Dinner.

On the evening of April 13th Dr. William Seaman Bainbridge gave a dinner at the Hotel Biltmore, New York, in honour of Dr. Eugene Hertoghe, of Antwerp, Dr. Alfred C. Jordan, of London, Dr. Benjamin Merrill Rickette, of Cincinnati, and other representatives of the uropean and American medical profession. About medical men were present.

New York University and Bellevue Hospital Medical School.

Dr. William Hallock Park, professor of bacteriology and hygiene in the New York University and Bellevue Hospital Medical College, has been elected dean of the college in the place of Dr. Egbert Le Fevre, who died recently.

The New Professor of Medicine at Johns Hopkins University.

Dr. Theodore C. Janeway, Bard professor of medicine at Columbia University and director of the medical department of the Presbyterian Hospital, New York, has accepted the chair of Medicine at the Johns Hopkins University, Baltimore, in succession to Dr. Lewellys F. Barker. Under the new scheme adopted recently at the University, professors will devote their whole time to teaching, the professors of surgery, Dr. W. S. Halstead, and pædiatrics, Dr. John Howland, having accepted the new conditions.

Cross of the Legion of Honour for Dr. Flexner.

The President of the French Republic has conferred the Cross of the Chevalier of the Legion of Honour on Dr. Simon Flexner, of the Rockefeller Institute.

Gold Medals for Surgeon-General Gorgas.

On April 22nd the National Academy of Sciences presented at Washington to Surgeon-General Gorgas its gold medal "for eminence in the application of science to the public welfare," and on April 27th the American Museum of Safety presented to him in New York its Dr. Louis Livingston Seaman medal. Both these awards were in recognition of his great achievements in the Canal Zone, Panama.

May 12th.

SOUTH AFRICA.

Proposed Registration and Medical Inspection of Domestic Servants and Children's Nurses.

IN connexion with an Ordinance before the Provincial Council to amend the general municipal law of the Cape Province the Administrator tabled a remarkable amendment. Under the existing law the council of a municipality may make regulations, *inter alia*, "for preventing the possible spread of infectious, contagious, or loathsome diseases by the carrying on of any trade, business, or occupation." The amendment provided that the following words should be added to the section—namely, "and providing for the registration and medical inspection of domestic servants and children's nurses in any area where the Administrator is of the opinion that such registration is necessary in order to prevent the spread of any contagious or loathsome disease." The proposal caused some outcry to be raised in Cape Town, but it was felt generally that very serious facts must have been brought to the notice of Sir Frederic de Waal to cause him to bring forward the proposal, and such proved to be the case when the Administrator dealt with the amendment in the Provincial Council. He stated that during the year he had made a long tour through Bechuanaland and Griqualand West, and that in the course of this tour the prevalence of syphilis was brought very forcibly to his notice not only by local authorities but by district surgeons, medical practitioners, and others. He was informed that the disease was very rife indeed amongst natives, and that it was spreading to the European section of the community. He stated that the disease differed considerably from syphilis as met with in other countries, and more particularly in its method of spread. While much of the disease was of hereditary origin, in acquired cases it seemed to be spread commensally and mainly by other means than by sexual intercourse. Apart from its method of spread and the absence of the earlier symptoms associated with syphilis, the disease resembled syphilis in every other respect, and the general opinion amongst medical men in the area was that the disease was syphilis modified by racial and climatic conditions. Sir Frederic de Waal then quoted from the annual reports of Dr. A. J. Gregory, the late medical officer of health, showing that from 1903 onwards up to the date of Union the medical officer drew repeated attention to this serious problem, and that these reports contained details of numbers of cases in which European children had been infected by native servants. He then quoted evidence issued since Union showing that the number of European families reported as having become infected in this manner was increasing. The disease in its earlier stages is usually mild but extremely contagious, and many of these people are infected without being aware of it. He finally stated that he had deliberately placed the motion on the order paper to direct attention to and to cause a discussion on a very grave state of affairs with a view of rousing and educating public opinion on a national danger. After an able and instructive speech the Administrator formally proposed the motion, indicating that after it had been discussed he intended to ask leave to withdraw it in order that he might consult the Medical Congress which is meeting in Kimberley in June next. From the debate which ensued there is little doubt but that the Administrator convinced the House, and that the motion would have been carried had he not withdrawn it. Indeed, he was only allowed to do so on the understanding that legislation would be introduced next year after the Medical Congress had been consulted.

Legislation for Infectious Diseases.

The Public Health Acts of the Cape Province are defective in several respects. Amongst other defects they do not provide local authorities with sufficient powers to remove patients suffering from infectious diseases to hospitals set apart for that purpose. Thus a person suffering from a proclaimed infectious disease can only be removed compulsorily if he is without proper accommodation, or is lodged in a room occupied by more than one family, or is on board a vessel, or is not under medical treatment, or is found homeless in a public place. The Cape Provincial Council has now empowered municipal councils to frame regulations "providing for the compulsory removal to and detention in hospital of persons suffering or believed by the health officer to be suffering from an infectious disease of any nature, provided that, except in the case of plague, cholera, or small-pox, no such regulations shall authorise such removal or detention if the medical practitioner, if any, in attendance shall notify the health officer that in his opinion there is no necessity for such removal or detention." This is a distinct advance on the existing law, but it would have been preferable perhaps if the section had been restricted to deal with diseases proclaimed as infectious or contagious diseases under the Health Acts and if the proviso had been omitted.

The Bloemfontein Hospital.

The old board of the National Hospital, Bloemfontein, ceased to exist on March 31st last, and up to the end of April the new board had not been constituted according to the terms of the Hospitals and Charitable Institutions Ordinance of the Province. The resident medical officer, matron, and secretary severed their connexion with the hospital on March 31st, but on representations being made by the outgoing board the two former consented to remain until May 31st, so as to enable the new board to advertise the posts early in April, when it should have come into being. The fault lies apparently in the administration department, and throughout April there has been no constituted authority in charge of the hospital, no official responsible for its financial administration, and no steps taken to fill the vacancies.

April 30th.

INDIA.

Health Officer of Karachi.

AT present the posts of health officer of the port of Karachi and chemical analyst of Sind are held by one officer. Owing to the altered conditions and growing importance of the port of Karachi the present arrangement is found to be inconvenient, and it is therefore proposed to separate the two appointments.

A Surgeon-General for Bengal.

The question of converting the post of Inspector-General of Civil Hospitals in Bengal into a surgeonship has been under consideration for some time, and a despatch on the subject has been sent home for the approval of the Secretary of State.

Tuberculosis Institute for Madras.

The Government of Madras have sanctioned a provincial contribution of Rs.2,18,527 in aid of the King Edward Memorial Fund for the establishment and maintenance of a tuberculosis institute in the presidency town, and invited the views of the memorial committee in regard to the location, construction, and management of the institute.

Colonel Henry Smith, I.M.S.

The War Department of the United States has recently asked Colonel Henry Smith, civil surgeon at Amritsar, for a signed photograph of himself. This they desire to add to their gallery of distinguished modern medical celebrities in the Army Medical Museum and Library at Washington.

Antimalarial Campaign in Southern India.

Dr. Milton, the officer in charge of the Southern India Planters' Association, has elaborated a comprehensive antimalarial scheme, the particulars of which are now before the Madras Government.

Bombay Medical Union.

The annual report of the Bombay Medical Union gives a record of excellent progress, and there are now over 180 members on the roll. Papers on numerous important subjects, including malaria prevention, have been read by distinguished members of the union. In reply to a letter from the Government of India with regard to bogus degrees and diplomas, an important resolution was passed to the effect that "the union approves of the proposed legislation by the Government of India regarding the use of bogus medical degrees, and respectfully begs to suggest that any institution granting titles, degrees, diplomas, or licences entitling to practise medicine under the guise of some system of medicine or other, but practically imparting only a crude and imperfect imitation of the Western system of medical science should also be brought within the purview of the proposed legislation." Other resolutions included the decision to draw up a representation concerning the medical services and submit this to the Royal Commission on Public Services in India. The finances of the union show a satisfactory balance in hand.

Plague in the Punjab.

Though the plague epidemic in the Punjab is not reaching the proportions of a bad year it is decidedly severe in one or two districts. There is, for instance, a sharp outbreak in the Hafizabad tahsil of the Gujranwala district. As Gujranwala is a district that has been infected pretty steadily since the early days of plague, the outbreak there this year does not seem to point to any large degree of immunity having been reached by the people. Experiments are being made by the plague staff in the Punjab in rat destruction by means of slow-burning squibs containing potassium nitrate and sulphur. The squib is wrapped in paper soaked in mustard oil. The experiments have so far given promising results, for the fumes have been proved to kill rat-fleas coming in contact with them in less than 30 seconds. As the rat-run is the breeding-place of the rat-flea—where it leaves its eggs and the larvæ are hatched out—it is hoped that the flea-population may be very greatly reduced, provided these experiments can be reproduced with similar results on a wholesale scale. The weak point about all smoking processes is that they are ineffective against rats lodged in rafters in the roofs of houses. So far it has been found impossible to discover a method of dislodging such rats.

The Strike at the Lahore Medical College.

The original cause of the strike of Lahore Medical College students was the alleged proceedings of a meeting of students connected with the London Hospital, and the refusal of Lieutenant-Colonel Sutherland to preside at the meeting of protest which the students in Lahore proposed to hold. The report was published in a Punjab newspaper. When Colonel Sutherland's attention was called to the matter he pointed out that there was nothing to show that the report was accurate, and he told the students' representatives that he would write to the dean of the hospital and ask for an authorised version of the proceedings. The students were, however, too indignant to wait; they held their meeting and decided to strike forthwith. The reply to Colonel Sutherland's letter has now been received, and is published as a press *communiqué* by the Punjab Government. The dean's letter completely justifies Colonel Sutherland's caution and his advice to the students. The original account of the meeting was garbled to such an extent that it can only be described as a malicious misrepresentation of perfectly innocent facts. The persons alleged to have proposed, seconded, and supported the resolution were not even present; the resolution actually passed bore no resemblance whatever to the resolution quoted by the correspondent of the Punjab newspaper. The statement that a resolution was passed by 462 votes to 21 condemning the admission of Asiatics to the London Hospital and the English medical profession was totally false. No such resolution was passed, and the only resolution proposed was accepted on a show of hands in a meeting at which about 150 persons were present. The dean further reports that Mr. Mallet, of the India Office, who was present, spoke warmly on behalf of Indian students, and that in general a distinction was frequently drawn between Indian and Egyptian students to the advantage of the former. The dean added a personal testimony to the general good conduct of Indian students and to the sympathy that is felt for them. Whatever may be the outcome of the inquiry about to be held into alleged grievances, it is now demonstrated that the strike in its origin was unjustified by any substantial cause.

April 23rd.

Correspondence.

"Audi alteram partem."

THE PLEA FOR IMMEDIATE OPERATION IN APPENDICITIS.

To the Editor of THE LANCET.

SIR,—There is one point in connexion with the question of immediate operation in cases of acute appendicitis raised by Mr. Battle and yourself in the issue of THE LANCET for May 16th which does not appear to me to have received the attention that it deserves. No clear distinction is drawn between "immediate" and "early," nor between the onset of the attack and the onset of the acute symptoms. An operation is spoken of as "early" because only a few hours have passed since the outbreak of the symptoms that caused alarm, while as a matter of fact the attack has perhaps been going on for two or three days. Acute symptoms, instead of marking the beginning of the disease, in only too many instances mean that the disease has suddenly changed its character and become acute.

I have operated within eight hours of the onset of the acute symptoms and found the whole of the appendix gangrenous. It was difficult to believe that such a change could have taken place within that time. More careful inquiry elicited the fact that there had been discomfort with a feeling of nausea for 48 hours before, only the patient thought nothing of it and went into the city as usual. The operation was really performed upon the third day, not upon the first. It was immediate, but not early. No one watching a mild case of appendicitis would hesitate about immediate operation if the symptoms suddenly became acute. The rule should be the same when the attack apparently begins with acute symptoms. Nearly always it will be found on inquiry in these cases that there has been "biliousness" or "stomach-ache" or a feeling of nausea for two or three days before. The patient will say nothing about it unless he is asked directly. Previous attacks of a similar character have often occurred before and have passed off. But on this occasion the attack means that the appendix is involved, and the beginning of the inflammation must be dated, not from the time the symptoms suddenly changed their character and became acute, but from the time when they first appeared. Immediate operation is as necessary in the one case as in the other, for the conditions are the same. But the operation cannot be called "early."

I am, Sir, yours faithfully,
C. MANSELL MOULLIN.

Wimpole street, W., May 17th, 1914.

ANKYLOSTOMIASIS.

To the Editor of THE LANCET.

SIR,—I am directed to inform you that the enclosed dispatch from H.M. Consul at San Juan, Porto Rico, has been sent by the Lord President of the Privy Council to the President of the General Medical Council for the information of the medical men in this country, and that it was accompanied by a pamphlet on Uncinariasis or Hookworm Disease, a copy of which is in the possession of the Medical Council.

I am, Sir, yours faithfully,
NORMAN C. KING,
Registrar.
Oxford-street, W., May 15th, 1914.

H.B.M. Consulate, San Juan, Porto Rico,
February 14th, 1914.

SIR,—In view of the increasing attention which is being given to the disease known as "uncinariasis" or hookworm disease, more commonly known as "anæmia," and which has been made a special study on this island, I have procured from Dr. C. R. Gill two copies of a technical record of 316 cases cured by him at Porto Rico during the period from April to September, 1912, which I have the honour to transmit, enclosed herewith, and trust may prove of interest to the British medical faculty.

The importance attached by the U.S.A. authorities to this branch of medical research is clearly demonstrated by the fact that during the fiscal year ended June 30th, 1912, no less than 43 stations were established for the treatment of sufferers from the disease in question. Of the 20,851 patients attended by the staff of the Bureau of Transmissible Diseases 24 per cent. were cured, leaving 61 per cent. under treatment. It has to be mentioned, however, that 13 per cent. who presented themselves at stations for treatment, and are included in the aggregate of attendance, failed to return.

Dr. C. R. Gill, who lectured before the Royal College of Surgeons, at the Liverpool School of Tropical Diseases, and to other medical corporations in England on his return from U.S.A. army medical work in the Philippine Islands, has very kindly expressed to me his willingness to answer any queries addressed to him by his British medical colleagues arising from matter treated in the pamphlet sent herewith.

I have the honour, &c.,
(Signed) G. AMBROSE POGSON,
H.B.M. Consul.

The Right Hon. Sir Edward Grey, K.G., &c.,
H.M. Secretary of State for Foreign
Affairs, Foreign Office, S.W.

THE MEDICAL INSURANCE AGENCY.

To the Editor of THE LANCET.

SIR,—I am glad to see Dr. G. E. Haslip's letter in THE LANCET of May 16th, and as a member of the committee of the Medical Insurance Agency I should like to say that I fully endorse everything it contains. There are two forms of insurance which should, I think, receive the early and earnest consideration of every member of the profession. The first of these is simple life assurance, which should be effected as soon as possible after qualifying, thus obviating the risk of having to pay a higher premium in later years owing to impaired health or other causes. The second is endowment insurance, which is particularly applicable when the education of children has to be provided for out of professional savings.

First, let me say a word as to simple life assurance. The assertion is often made that there is no need for a bachelor to insure his life, but it seems to me that the sooner this fallacy is dispelled the better. In the first place, the regular payment even of a small annual premium encourages thrift. Secondly, the views held by most people as to the advantages and disadvantages of matrimony are notoriously liable to modification as time passes. And thirdly, even if the idea of marriage be finally abandoned the life assurance which has been effected will always be a valuable asset, seeing that the surrender value of the policy may at any time be realised, either to meet an unexpected financial strain or to purchase an annuity on retirement from practice. The second form of insurance is one which it is generally advisable to effect as soon as the returns from practice are sufficient. It should ever be borne in mind by the practitioner with a young family that the high-water mark in educational expenditure often coincides with the low-water mark of practice. Failing health, advancing years, inexorable competition—these are the contingencies that a careful man should do his utmost to insure against. I know of nothing more distressing than for a man who has had, and still has, modest ambitions for his children suddenly to find himself in middle age unable to carry out his plans, and perhaps his promises. However pressed a young married man may be, it is certainly his duty carefully to consider the best and most economical way of insuring his life.

As Dr. Haslip has stated, all medical men who insure through the Medical Insurance Agency are able to effect a material saving in commissions, whether the insurance relate to life, accident, fire, burglary, motor-car, or employer's liability. But there is an additional inducement which I feel sure will appeal to all your readers. It is that the medical man who thus insures not only benefits himself but many charities closely connected with his own profession. As Dr. Haslip has stated, our committee is able (thanks to the support the agency has already received, and to the energy of our agent and secretary) to disburse from our profits considerable sums each year to such charities.

I am, Sir, yours faithfully,
FREDERIC HEWITT.
Queen Anne-street, W., May 18th, 1914.

DIATHERMY IN VESICAL HÆMORRHAGE.

To the Editor of THE LANCET.

SIR,—I was interested to read the letter of Dr. C. E. Iredell and Mr. Ralph Thompson on this subject in your last issue, for it surprised me a little to find that Mr. R. H. Jocelyn Swan made no reference to diathermy in his paper on Tumours of the Bladder.

The application of diathermy through the cystoscope to villous tumours of the bladder was devised by Beer, of New York, two years ago, and has since been used with uniform success in some hundreds of cases. I have been employing it for a long time, and published what I believe to be the first English paper on the subject in the *Clinical Journal* of April 15th, 1914. The results are so satisfactory that I do not believe the bladder need ever be opened in the future for simple tumours of the bladder. I find that three or four treatments are usually quite sufficient to destroy a papilloma completely. No anæsthetic is required and the patient need not remain away from work for more than a day for each treatment.

I think it most important that knowledge of this treatment should become widely disseminated amongst the medical profession. Personally I hope never to open a bladder again for simple villous tumours, as I am convinced that such tumours can all be cured by diathermy applied [illegible] aid of the cystoscope.

I am, Sir, yours faithfully,
FRANK KIDD.
[illegible] ...th, 1914.

MASSIVE COLLAPSE OF THE LUNGS.

To the Editor of THE LANCET.

SIR,—The interesting paper of Dr. T. R. Elliott and Dr. L. A. Dingley in THE LANCET of May 9th on post-operative massive collapse of the lungs was only this week brought to my notice. I have been working for some time on this interesting subject, experimentally and by making clinical observation, and as my conclusions do not agree with those of the authors I venture to write this letter.

Massive collapse of the lung is by no means limited to those who have undergone operations, but symptoms such as those described in the paper are generally only found in patients who have had an anæsthetic. It is well known to infirmary medical officers that the lower lobes of the lung are, on post-mortem examination, found more or less completely collapsed in patients who have been bedridden for some time and without any symptoms of such lesions being present during life. I have two specimens taken from patients who were completely paraplegic, from lesions in the upper dorsal region of the spinal cord, showing complete collapse of the lower lobes, thus indicating that the condition occurs when the diaphragm is the sole muscle of respiration. Further, many patients who have been lying supine—e.g., under treatment for fracture of the femur or other conditions—exhibit the physical signs of massive collapse of the lower lobes. In all the cases I have investigated there has been loss of tone of the abdominal muscles on the side affected or on both sides when both the lower lobes are collapsed. When one side only is affected, that side will be found by measurement to be larger than normal—a point which is against the theory of spasm of muscles. I do not propose to enter upon a discussion as to the part played by the abdominal muscles in respiration, but I am led to the conclusion that massive collapse of the lower lobes is a natural sequence of prolonged quiet breathing in the supine position in such people as do not then use the abdominal muscles to fix their chests. The mechanism of this collapse is evidently closely connected with that of the production of œdema of the lungs, the distribution of the two conditions corresponding fairly closely. Sometimes after laparotomy the action of certain of the abdominal muscles is completely inhibited and collapse may follow even though the patient is not in the supine position. To some extent the form of the chest plays an important rôle. The greater the comparative transverse diameter of the chest at its lower part, the greater is the liability to collapse. It is easy to demonstrate that marked differences in the measurements of the chest and position of the diaphragm occur when changing from the upright to the supine position. By means of X ray examination it can be demonstrated that in quiet breathing the movement of the diaphragm may be so slight as to be practically negligible, and this fact must be taken into account when concluding that there is no movement of the muscle in pathological conditions.

The results of the experiments recorded are in agreement with my own, but it must be remembered that the chest of an animal, such as the rabbit, is very different from that of the average man. My experiments show that section of one phrenic nerve produces but little effect, but that effect is distributed over both lungs. I agree also with the treatment suggested, which is very similar to that which I laid down in an article on this subject in the "Practitioner's Encyclopedia of Medicine and Surgery," second edition.

I am, Sir, yours faithfully,

J. CHARLTON BRISCOE.

Harley-street, W., May 19th, 1914.

SOUTH AFRICAN CIVIL SURGEONS' DINNER.

To the Editor of THE LANCET.

SIR,—The above dinner (now held triennially) will take place on Wednesday, July 8th, at the Criterion Restaurant, at 7.45 P.M. Dr. Howard Tooth will take the chair. Tickets, price 10*s.* 6*d.*, should be paid for at the dinner.

It is hoped that those who wish to attend will communicate with one of the undersigned *as soon as possible*, in order that the necessary arrangements for the dinner may be carried out.

We are, Sir, yours faithfully,

F. E. FREMANTLE,
County Medical Office, Hertford.
C. GORDON WATSON,
82, Harley-street, W.

May 19th, 1914.

FUCHSIN IN SOFT CHANCRE.

To the Editor of THE LANCET.

SIR,—I do not know whether fuchsin (aniline red) has ever before been used in the treatment of soft chancres. Perhaps some of your numerous readers may enlighten me on the subject and give me references.

Fuchsin in a 5 per cent. ointment with vaseline has been found of some benefit in the treatment of carbuncles, and that led me to try it in soft chancres. During the last month I have treated nine cases of undoubted soft chancre with so much benefit that I am convinced that there is no other drug which is so useful. Under ordinary treatment soft sores take about six weeks to heal up, while with fuchsin I have been able to heal them in less than two weeks. All my nine cases were of multiple chancres (from two to four), and the average duration of treatment works out at eight days. The longest is ten and the least is four days.

Two of my cases deserve special notice. One of them was complicated with an enlarged bubo in the left groin as large as a small orange. The chancre was about 1 in. by ¼ in., with a foul base. With fuchsin ointment this healed up in six days, and the bubo, which had threatened to suppurate, at once subsided, especially as the source of infection was brought under control in two days. The second case had been going on for a little over three weeks, with one large and three small ulcers. Caustics had already been applied twice by another doctor, without much benefit. So he came to me. Under fuchsin treatment I was able to heal them in 10 days. I usually prescribe a 5 per cent. ointment in vaseline of fuchsin (aniline red) to be applied to the chancre, after first washing and then drying it. If the prepuce can be brought over the glans penis no other dressing is required, although it must be noted that it stains the linen red, which is its only drawback. I ask the patient to clean the parts and apply the ointment twice a day, simply because it is difficult to get poor people to learn the benefits of keeping them clean. Otherwise, in my opinion, a single application in 24 hours will quite suffice. The ointment, when it is not freshly made, is of a beautiful red colour, but when freshly made does not look nice.

At first I applied caustics, like nitric acid, to destroy the superficial bacteria and infected tissues. But I have found that it is not at all necessary. The ointment when applied even to the most foul ulcers clears up everything, and within 48 hours I have always seen granulations springing up. The necessity of caustics, the pain, and the mental agony of the patients, are thus relieved. The effect of fuchsin seems to correspond in some respects to that of scarlet red—viz., rapid epidermisation; but over and above this the antiseptic effect which I have noticed in fuchsin is not found in scarlet red, though I must confess I have not given the latter a fair trial in such cases. Fuchsin ointment in a greater strength than 5 per cent. may irritate the parts.

It is of no benefit in hard chancres. I tried it in two cases. Both, according to their statements, were the worse for it. On inspection I found the chancres ulcerating and discharging pus.

I am, Sir, yours faithfully,
CHHAGAN H. KANTAWALA, M.R.C.S. Eng.,
Bombay, April 25th, 1914. L.R.C.P. Lond.

⁂ Fuchsin is known to have an antiseptic action, and it has been employed to a slight extent in the treatment of trypanosomiasis and occasionally for chronic ulcers, but so far as we are aware it has not hitherto been used for soft chancres. The beneficial action described by our correspondent is doubtless due to its antiseptic power and not to stimulation of the epidermis, for scarlet red, which causes much greater stimulation of the epidermis, has no antiseptic power.—ED. L.

THEORIES OF HYSTERIA.

To the Editor of THE LANCET.

SIR,—The interesting fact reveals itself from a consideration of Dr. J. A. Ormerod's lecture in THE LANCET of May 9th on the Freudian Theory of Hysteria, and from other similar writings recently published, that criticism against Freudian psychology is becoming a good deal less confident and emphatic than formerly. Any criticism in Dr. Ormerod's article beyond simple exposition of the subject under consideration was markedly tentative and vigilantly non-committal. It will be instructive to observe if this is the mark of a changed attitude on the subject.—I am, Sir, yours faithfully,

FREDERICK DILLON, M.B., Ch.B. Edin.
Leicester Borough Mental Hospital, May 14th, 1914.

THE FATALITY OF MEASLES.

To the Editor of THE LANCET.

SIR,—It seems to me that the question of the fatality of measles, referred to by Dr. J. Gordon Sharp in THE LANCET of May 9th, can only be solved when the cause of the disease has been settled. Experience of malaria, Malta fever, plague, yellow fever, sleeping sickness, and the other successfully combated affections seems to show that until we have a complete knowledge of their natural history they cannot be prevented.

Two years ago I described cell-inclusions in the blood of acute measles cases similar to those I have described in syphilis and in scarlet fever. And although I have suggested that these "bodies" are parasites and that they may be amenable to salvarsan and mercury, and have published these suggestions, little or no attempt has been made to give this method of prevention an organised trial. If these cell-inclusions are protozoal parasites and really resemble those found in human and animal syphilis, their treatment with these drugs, if continued, like quinine in malaria, until convalescence is established in all cases, should considerably lower the incidence of measles.

These cell-inclusions can be found in the peripheral blood cells of acute measles so long as the fever lasts; then they are present in the nasal and aural pus, as well as in the abscess pus for long periods. I have found them thus in every case examined up to the present time. Therefore I think the method of preventive treatment is worth a trial. I proposed giving an initial dose of 0·1 to 0·2 grm. of salvarsan intravenously, or for small children a small dose of a weak alkaline solution hypodermically; and this repeated a week later. Then each case should be given either mercury or arsenic in amounts according to practice and similar to that employed in congenital syphilis, until all peeling or purulent discharges have ceased. If, as I believe, these bodies are parasites, they should possess an extracellular phase, and then the drug should affect them, as quinine does in malaria. Such treatment is harmless, for children take arsenic well, and in the absence of any other method of prevention it may be productive of good results. I have tried it in a few cases which Dr. F. F. Caiger put at my disposal; but it must be given an organised trial on a large scale before we can judge justly of its effects. The idea is to bring about an immediate reduction of parasites and to prevent their further spread.

I am, Sir, yours faithfully,
E. HALFORD ROSS.
The Lister Institute of Preventive Medicine,
Chelsea-gardens, S.W., May 11th, 1914.

AN IMPORTANT CORRECTION.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to correct an unfortunate error in the "Annual Reports" of the Royal Dental Hospital of London, School of Dental Surgery, for 1913, just issued. Mr. Frank V. Richardson, whose name was included in the Obituary Notice, is, I am glad to say, still alive and well. I am, Sir, yours faithfully,

May 14th, 1914. THE EDITOR OF THE REPORTS.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Henry James Casey, of Tunbridge Wells, the testator left £6000 to the Walthamstow, Leyton, and Wanstead Children's and General Hospital for the endowment of six beds to bear his name and that of his wife.—The late Mr. Henry Griffith has left £500 to the Brompton Cancer Hospital.—The late Mr. J. Richardson, of Bath, has bequeathed £500 each to the Royal United Hospital, Bath; the Royal Infirmary, Liverpool; and St. Mary's Hospital, Paddington.—The late Miss Jane Whipp, of Merlewood, Prestwich, Lancs., left by will £300 to the Bury Dispensary Hospital.—Failing issue to the legatee the late Mrs. Edna Howarth, of Langdale Chase, Windermere, Westmorland, left by will certain sums to provide a wing in the Manchester Children's Hospital, Pendlebury.—By her will the late Mrs. Mary Ann Wingrove, of Southampton, left the residue of her estate, amounting to some £17,000, to be equally divided among eight charities, including Dr. Barnardo's Homes, the Devon and Exeter Hospital, Exeter, the Royal South Hants and Southampton Hospital, Southampton, and the Cancer Hospital, Brompton.—The late Mrs. Mary Elizabeth Booth, of Redhill, Surrey, left £400 each to the London Hospital, the University College or North London Hospital, the Children's Hospital, Paddington Green, and St. Mary's Hospital, Paddington.—The late Miss Sarah Anne Adams, of Coventry, Warwickshire, has left £1000 each to the Walsall Cottage Hospital, the Birmingham General Hospital, and the Coventry and Warwickshire Hospital.

THE NATIONAL INSURANCE ACT.

THE DRUG FUNDS IN SCOTLAND.

THE Scottish Insurance Commissioners have addressed a circular letter to panel practitioners in Scotland asking them for their views on the proposal made by the pharmacists that the fees for dispensing medicines for insured persons should be raised. The present fee for dispensing liquid preparations is 2*d.* for those up to and including 8 oz., and 3*d.* for more than 8 oz., with an extra fee of 2*d.* if the medicine contains an emulsion. The proposed new fee is 4*d.* for all liquid preparations of any kind and size. Similarly it is proposed to alter the dispensing fees for powders, pills, ointments, &c. The reason why the Commissioners are consulting panel doctors is because of the possibility that the proposed new fees might in some districts cause an encroachment on the "floating sixpence." The number of prescription forms used by doctors during the first medical year was equivalent in burghs to 1·92 in respect of every insured person, and in counties to 1·58. The new fees would increase the cost of each prescription by about 1¾*d.*, making the average fee in burghs 3·36*d.* and in counties 2·76*d.* An examination of the returns from all districts in Scotland shows that in 27 areas the increased rates could probably be allowed without trenching on the "floating sixpence," but that in 16 areas they would probably entail some encroachment, and in 15 districts in which the charge of 1*s.* 6*d.* per insured person was last year not sufficient to meet the drug bills the new fees would entail a further encroachment on the "floating sixpence." Scottish panel chemists base their claims for dispensing fees higher than those in the English tariffs on various grounds. They claim that in England the amount of medicine consumed per patient is greater than in Scotland; that in England the period for which mixtures are prescribed to last is shorter, leading to more frequent "repeats," and consequent dispensing fees. Scottish chemists also point out that whereas in England the Insurance Act had the effect of directing an increased volume of trade into the chemists' hands, in Scotland it merely changed a large proportion of the chemists' private clients into insured clients.

EXETER INSURANCE COMMITTEE.

At a meeting of the Exeter Insurance Committee the Medical Benefit Subcommittee reported negotiations which had taken place with regard to the allocation of insured persons who had not chosen their medical attendants. The subcommittee had had interviews with representatives of the medical men on the panel and with the panel subcommittee, and it recommended that a joint committee should consider the matter. This was adopted. Notice was given of a motion by a member of the committee:—

> That the panel doctors be informed that the agreement entered into with them on July 1st, 1913, as to the division of the funds accumulated in respect of insured persons who have not selected a doctor expired on Oct. 12th, 1913, and this committee considers itself free to deal with such accumulations in such manner as it thinks desirable.

SHEFFIELD INSURANCE COMMITTEE.

The Medical Benefit Subcommittee at Sheffield presented a report upon a charge against a member of the panel who had admitted that he had given certificates of incapacity to a man who during the time covered by some of them was to his knowledge in prison. The certificates were given after the patient's discharge, when for one week he remained unfit for work, and the defence of the medical practitioner was that the man was in fact in a condition of illness which rendered him incapable of work during the period of his imprisonment. It was pointed out that each certificate stated that the patient had been examined on the date on which the certificate was given, and in accordance with the report of the subcommittee the Insurance Committee censured severely the medical man reported upon, the chairman observing that the subcommittee's recommendation erred on the side of leniency.

PHARMACISTS AND THE DEFICIENCY IN THE DRUG FUNDS.

At the May meeting of the Council of the Pharmaceutical Society a report from the association's executive committee was received and adopted, which stated that the committee had resolved "that the secretary should take immediate steps to secure a complete report of the facts in all the deficiency areas in England and Wales as a preliminary necessary to initiating effective national action." A committee of pharmacists has been appointed to meet a similar committee of the British Medical Association in connexion with the revision of the drug tariff and collateral matters.

PRESENTATIONS TO MEDICAL MEN.—A numerous and representative gathering of Llandudno residents took place in the town hall on May 13th to witness a public presentation to Dr. Thomas Dalton, on his retirement from practice, in recognition of his services to the town during almost half a century as a medical practitioner and as a public man. Lord Mostyn presided, and Lady Mostyn, on behalf of the subscribers, presented Dr. Dalton with a valuable service of silver plate. A letter was read from the secretary of the Queen of Roumania expressing Her Majesty's feelings of esteem and gratitude for Dr. Dalton, and associating herself whole-heartedly with the homage which his numerous friends wish to offer to him at the close of his professional career. Later in the evening Dr. Dalton was entertained at a complimentary banquet at the Imperial Hotel, Colonel Lloyd Mostyn presiding, and among the guests were most of the medical practitioners of the town and district.—Mr. W. Percy Blumer, F.R.C.S. Edin., of Sunderland, who has resigned the appointment of honorary surgeon at the Sunderland Royal Infirmary on leaving for London, has been presented with two framed photographs of himself, in recognition of his valuable services to the infirmary. One of the photographs will remain in the infirmary.—Mr. C. J. W. Pinching and Dr. C. Firth were presented at the monthly meeting of the committee of management of the Gravesend Hospital held on May 18th (the birthday of both recipients) with silver inkstands bearing the following inscriptions:—"To Charles John William Pinching, Esq., M.R.C.S. Eng., M.S.A., by the President, Vice-Presidents, Trustees, Hon. Auditors, Committee of Management, and his colleagues on the Medical Staff, in appreciation of thirty-six years' service as Honorary Surgeon to the Gravesend Hospital. May 18th, 1914." "To Charles Firth, Esq., M.D. Lond., F.R.C.S. Eng., by the President, Vice-Presidents, Trustees, Hon. Auditors, Committee of Management, and his colleagues on the Medical Staff, in appreciation of thirty-one years' service as Honorary Surgeon to the Gravesend Hospital. May 18th, 1914." The presentations were made by Lord Darnley, who, in thanking Mr. Pinching and Dr. Firth for their work for the hospital, said it had been his lot to hear a certain number of hard things said about the doctors in connexion with their work among the poorer classes, but it was his very firm belief that there was no class of the whole community who gave so much voluntary help, both in their private practice and in their services to the hospitals, as the doctor.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of Comitia of the Royal College of Physicians on April 30th, and of the Council of the Royal College of Surgeons on May 14th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred by each College on the following 105 candidates, who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Examining Board:—

Francis Dighton Annesley, Guy's Hospital; David Charles Gordon Ballingall, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Irene Bastow, Royal Free Hospital; Stanley Samuel Beare, L.D.S. Eng. Middlesex Hospital; Howard Alexander Bell, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Sadashiv Vaman Bhat, L.M. & S. Bombay, Bombay University and Middlesex Hospital; Henry Cecil Billings, London Hospital; Sydney Guy Billington, M.B., B.S. Lond., Birmingham University; Auguste Rene Bourgault-Ducondray, University College and London Hospital; Ernest Cordley Bradford, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; John Ebenezer Kelly Brown, M.B., Ch.B. New Zealand, University of New Zealand and London Hospital; William Burt, St. Thomas's Hospital; George Maclean Campbell, Bristol University; Samuel Caplan, St. Mary's Hospital; Francis Laird Cassidi, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Arthur Chance, M.B. Dub., Dublin University; Harold Garrett Chaplin, St. Thomas's Hospital; Francis Howard Cleveland, St. Bartholomew's Hospital; Gerald Cock, Charing Cross Hospital; Gideon Robert Ernest Colquhoun, Cambridge University and St. George's Hospital; Edward Worthington Connolly, M.D., Kingston University and University College Hospital; Geoffrey Moore Cowper, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Thomas Hungerford Cresswell, L.M.S.S.A., Middlesex Hospital; Christopher Dean, B.A. Oxon., Oxford University and Guy's Hospital; Arthur Wesley Dennis, B.A. Oxon., Oxford University and St. Thomas's Hospital; Ismail Fahmy Diay, Cairo Medical School and Guy's Hospital; Mary Agatha Doherty, M.B. Toronto, Toronto University and Royal Free Hospital; Eric Donaldson, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Robert Ellis, Birmingham University and St. Bartholomew's Hospital; George Cranston Fairchild, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Septimus Alexander Forbes, London Hospital; Sourendra Mohon Ghosh, L.M. & S. Calcutta, Calcutta University; Frank Brayshaw Gilhespy, University College Hospital; Charles Leonard Gimblett, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Charles Hart Medlicott Gimlette, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Samuel Sowray Greaves, Leeds University; James Herbert Hadaway, Middlesex Hospital; Moustafa Hammouda, Cairo Medical School and University College Hospital; Mohammed Zaky Hanafy, Guy's Hospital; Thomas Watson Hancock, London Hospital; Arthur Geoffrey Patteson Hardwick, London Hospital; Arthur Dodsworth Haydon, B.A. Cantab., Cambridge University and St. Thomas's Hospital; John Higgins, St. Mary's Hospital; Norman Hodgson, M.B., B.S. Durham, Durham University; James Dennistoun Jones, B.A. Cantab., Cambridge University and London Hospital; John Herbert Jordan, B.A. Cantab., Cambridge University and Middlesex Hospital; Mildred Archer Jukes, Royal Free Hospital; Rustam Murwan Kharegat, B.A. Bombay, Bombay University and University College Hospital; Harold Dunmore Lane, London Hospital; Frank Winter Lawson, Guy's Hospital; David Llewellyn Lewis, London Hospital; Harry Audley Lucas, Cambridge University and Middlesex Hospital; Charles Virgil Nunuz Lyne, King's College Hospital; Arthur Griffith Maitland-Jones, London Hospital; Edward Graeme Martin, B.A. Cantab., Cambridge University and Guy's Hospital; Owen David Baker Mawson, London Hospital; Tottakat Krishna Menon, Madras Medical College and Charing Cross Hospital; Vivian Mercer Metivier, St. Bartholomew's Hospital; Henry Felix Mullan, London Hospital; Frank Andrew Miller Nelson, London Hospital; Harold Parker, Leeds University; Gwilym Rhys Pennant, University College of South Wales, Cardiff and London Hospital; Mahamarakelegey Gregory Perera, Ceylon Medical College and London Hospital; Frederick Stanley Lawrence Piggott, Cambridge University and St. Thomas's Hospital; Alexander Frederic Potter, St. Thomas's Hospital; Edna Mary Powell, Royal Free Hospital; Ibrahim Ibrahim Abdel Rahman, Cairo Medical School and University College Hospital; John Beaufoy Randall, B.Sc. Lond., University College and St. Bartholomew's Hospitals; Pierre Joseph François Louis Rathier du Verge, Guy's Hospital; John Rawlings Rees, B.A. Cantab., Cambridge University and London Hospital; Geoffrey Bower Richardson, St. Bartholomew's Hospital; James Wilson Richardson, M.D., C.M. McGill, McGill University and London Hospital; Cecil Arthur Robinson, St. Mary's Hospital; Arthur Norman Rushworth, Cambridge University and St. Bartholomew's Hospital; Ahmed Sabri, Cairo Medical School and St. Thomas's Hospital; Alexander Elder Saunderson, Liverpool University; Philip Savage, Guy's Hospital and Durham University; Claude Justin Scholtz, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Allan Seddon, M.B., Ch.B. Liverpool, Liverpool University and London Hospital; Gerard Prideaux Selby, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Bager Zainulabedin Shah, Bombay University and St. Bartholomew's Hospital; Mohammad Sharaf, Cairo Medical School and St. George's Hospital; John Edward Sharp, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Herbert Sharpe, B.A. Cantab., Cambridge University and Guy's Hospital; Lewis Wilton Shelley, B.A. Cantab., Cambridge University and St. Thomas's Hospital; George Holmes Smith, L.D.S. Eng., St. Mary's Hospital; Leslie Muir Smith, Guy's Hospital; Thomas Victor Somerville, London Hospital; Edward Benjamin Sunderland, University College Hospital; William Edmund Taylor, Bristol University; Thomas Harold Thomas, London Hospital; Alexander Wilmot Uloth, Cambridge University and St. George's Hospital; Sadanvala Bashiam Venugopal, L.M. & S. Madras, Madras Medical College and Guy's Hospital; Vernon Charles Whitby Vickers, Cambridge University and St. Mary's Hospital; Robert Allez Rotherham Wallace, M.B., Ch.M. Sydney, Sydney University and St. Bartholomew's Hospital; Francis Clark Watson, Oxford University, St. Thomas's, and St. George's Hospitals; George William Watson, Leeds University; Leslie Gordon White, Leeds University; Henry Parks Whitworth, Guy's Hospital; Hugh Lawrence Widdowson, M.B., Ch.B. New Zealand, University of New Zealand; Stanley Murray Wilcox, Cambridge University and St. George's Hospital; Sydney Arthur Wilkinson, St. Thomas's Hospital; Richard Williams, London Hospital; Alfred Wills, Guy's Hospital; Arthur Graham Winter, London Hospital; and Kenneth John Yeo, Cambridge University and London Hospital.

Diplomas in Tropical Medicine and Hygiene were granted to the following four candidates:—

Vivian St. John Croley, L.R.C.P. & S. Edin., and L.F.P. & S. Glasgow, Edinburgh University and London School of Tropical Medicine; Gordon Gray Jolly, Capt. I.M.S., M.B., Ch.B. Edin., Edinburgh University and London School of Tropical Medicine; Maharaj Krishna Kapur, L.M. & S. Punjab, Lahore Medical College; and Andrew Murphy, Major I.M.S., M.B., Ch.B., Royal University of Ireland, Cork and London School of Tropical Medicine.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the First Professional Examination in Anatomy and Physiology for the diploma of Fellow of the above College, held on May 6th, 7th, 12th, 13th, 14th, and 15th, 122 candidates presented themselves for examination, of whom 40 passed and 82 were rejected. The following is a list of the successful candidates:—

Arthur Wilfrid Adams, Bristol University and London Hospital; Lalit Mohan Banerji, M.S. Calcutta, Calcutta Medical College and St. Bartholomew's Hospital; Charles Harrison Barber, Captain, I.M.S., B.A. Oxon., M.R.C.S., L.R.C.P., Oxford University and King's College Hospital; John Hamilton Barclay, M.B., B.S. Durh., M.R.C.S., L.R.C.P., Durham University and London Hospital; Lyle John Cameron, M.D. Manitoba, University of Manitoba, Canada, and King's College; Norman Brandon Capon, Liverpool University; John Beresford Christian, Major, I.M.S., M.R.C.S., L.R.C.P., St. George's Hospital and King's College; Robert Hood Fleming, B.Sc. Lond., Middlesex Hospital; Thomas Gordon Fleming, M.B., B.S. Adelaide, Adelaide University and London Hospital; Alexander Galletly, M.B., Ch.B. Edin., Edinburgh University and King's College; John Gilmour, Durham University; George Turner Gimlette, B.A. Oxon., Oxford University and St. Thomas's Hospital; Arthur Oliver Gray, M.R.C.S., L.R.C.P., Middlesex Hospital; Douglas Green, M.B., B.S. Lond., Sheffield University and St. Bartholomew's Hospital; Frank Keith Hayman, Bristol University and London Hospital; Thomas Albert Hindmarsh, M.B., B.S. Durh., M.R.C.S., L.R.C.P., Durham University and London Hospital; George Philip Buckingham Huddy, London Hospital; Edgar Howard Lake, Middlesex Hospital; Mary Francis Lucas, M.B., B.S. Lond., Royal Free Hospital; Frederick Buick McCarter, B.A., M.B., B.Ch., B.A.O. Dub., Dublin University; Rodney Honor Maingot, St. Bartholomew's Hospital; Charles Bertram Marshall, M.D., B.S. Manch., Manchester University; Frank Beauchamp Martin, M.B., B.S. Melb., Melbourne University and Middlesex Hospital; Vaman Raghunath Mirajkar, L.M. & S. Bombay, Bombay University and St. Bartholomew's Hospital; John Kerr Muir, Middlesex Hospital; Charles Noon, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Aubrey Radford, M.B., Ch.B. Edin., Edinburgh University; Griffith James Randall, B.Sc., University College, Cardiff, and Westminster Hospital; Nicol McNicoll Rankin, M.B., Ch.B. Glasg., Glasgow University, Middlesex and London Hospitals; Louis Carnac Rivett, M.R.C.S., L.R.C.P., Cambridge University and Middlesex Hospital; Harold Bedford George Russell, M.A., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Bartholomew's Hospital; Henry Richard Sheppard, St. Thomas's Hospital; Archibald Walter Scot Skirving, M.B., C.M. Sydney, Sydney University and University College; Norman Armitage Sprott, B.A. Oxon., Oxford University and St. Thomas's Hospital; James Swan, M.B., Ch.B. Edin., Edinburgh University and London Hospital; Sydney William Frank Underhill, B.A. Oxon., Oxford University; Cecil Pembrey Grey Wakeley, King's College; William Tom Warwick, B.A. Cantab., Cambridge University and Middlesex Hospital; William Edwin Wilson, St. Bartholomew's Hospital; and Alberto Medardo Zamora, M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and Guy's Hospital.

At a meeting of the Council of the College held on May 14th Licences in Dental Surgery were conferred upon 41 candidates who have passed the necessary examination and have complied with the by-laws. The following is the list of successful candidates:—

Gerald Beaumont Ash, B.A. Cantab., Middlesex and Royal Dental Hospitals; Alexander Douglas Ball, Charing Cross and Royal Dental Hospitals; John Walter Beacock, Guy's Hospital; William Milton Bull, London Hospital; Donald Clewer and Arthur Hedley Cole, Guy's Hospital; Henry Robert Pyement Collett, Manchester University; Henry Charles Corke and George Lambert Cutts, Guy's Hospital; Arthur Thomas Dally, Middlesex and Royal Dental Hospitals; Ulysses James Garfield Dancer, Birmingham University; Robert Lester Dunn, Victor Robert Dyke, and Herbert James Edwards, B.A., Guy's Hospital; Gilbert George Ellis, Manchester University; Alan Basil Hacking, Middlesex and Royal Dental Hospitals; William Cecil Hammond-Williams, Guy's Hospital; Albert Ernest Henry, B.Sc. Birm., Birmingham University; Reginald John Inder, Middlesex and National Dental Hospitals; Thomas Henry Jackson, Charing Cross and Royal Dental Hospitals; Henry Jennings, Liverpool University; Sydney Emil Johnson, Guy's Hospital; Lionel Everitt Markham, Durham University; George Douglas Moore, Middlesex and Royal Dental Hospitals; Glenn Fowler Musson, Leeds University; Winifred Amelia Oaten, Royal Free and National Dental Hospitals; Frank Henry Parsonage, Manchester University; Thomas Harold Parsons, Birmingham University and London Hospital; Reginald Jack Pickett, Guy's Hospital; Ernest Russell Ray, Middlesex and Royal Dental Hospitals; Alfred Thomas Rycroft, Ernest Charles Rycroft, and Harold Obesrt Salt, Guy's Hospital; Leslie Bacchus Smith, Middlesex and Royal Dental Hospitals; Hubert Horace Stones, Manchester University; Norman David Swayne Straton, Charing Cross and Royal Dental Hospitals; Frederick Edward Alan Thorman, Birmingham University; Maurice George Whitten, Guy's Hospital; Arthur Stuart Whitworth and Keith Eric Wood, Middlesex and Royal Dental Hospitals; and John Edward Wright, Guy's Hospital.

THE LORD MAYOR TRELOAR CRIPPLES' HOSPITAL AND COLLEGE, ALTON.—The first festival dinner of this hospital and college was held in the hall of the Merchant Taylors' Company on May 13th, those present numbering about 150. The chair was taken by the Right Hon. A. J. Balfour, M.P. The medical men present included the Master of Downing, Sir Bertrand Dawson, Mr. J. Berry, Mr. F. F. Burghard, Mr. O. L. Addison, Dr. F. Batten, Mr. John Morgan, C.V.O., Mr. H. S. Pendlebury, Mr. Walter Edmunds (members of the honorary medical board), Mr. H. J. Gauvain (resident medical superintendent), Dr. Guy Stephen, Mr. D'Arcy Power, Dr. Henry Hetley, and Sir Charles Wyndham, who forsook practice for the stage so many years ago that few remember his connexion with the medical profession. Mr. Balfour, in proposing the toasts of "The King" and of "The Royal Family," said that though it was usual to present these toasts with few words he must remind his hearers that it was largely due to the energy of the Royal Family that the hospitals of the metropolis were on their present basis. The Queen and Queen Alexandra especially had shown their interest in them, and the latter particularly with reference to this hospital. In proposing the toast of "Prosperity to the Alton Hospital and College" Mr. Balfour said that he would lay down the proposition without fear of contradiction that they could feel assured that money given in support of the hospitals of this country would lessen human suffering and increase human efficiency and happiness, and would not be wasted. He dwelt on the threefold work of hospitals—viz., (1) the alleviation and prevention of human suffering; (2) means for medical education; and (3) promotion of research. He dwelt on each point, and with regard to the last said he did not think it would be possible to exaggerate the change that had come over medical practice during his own recollection, and he could not doubt that they were on the verge of great developments. No branch of scientific research had had more beneficial results than medical science, and he urged that they should take their national share in that international work. As to the Treloar Hospital, he had visited it last year, and was so impressed by all that he saw there that he felt that every humane man and every woman should give it their warmest support. The main work was to deal with those of tender years whose whole future if they survived would be overshadowed by this disease, tuberculosis, which if taken in time could be successfully dealt with. The place of this hospital could not be supplied by any other hospital or institution whatever, for a special institution was essential for the work. Alton Hospital combined all that could be given both by a hospital and by a sanatorium. The patient was received under conditions suited to his disease and treated as long as the case required; his subsequent course was followed, and if a relapse occurred he could be again received and treated by those who knew the early history of his case. He asked them to contribute to what was an assured success, and he felt confident that in so doing they would contribute to the felicity of the human race and to the relieving from a life-long burden of those who could neither help themselves nor ask for help. The list of donations was then read, amounting, with two donations of £1000 each, to £6731. Sir William Treloar, in responding, said they had now built a nurses' home to accommodate 35 more nurses, and to be called Queen Alexandra's Home. This would enable them to take 50 more children in addition to the 220 they always had. Mr. Gauvain replied for the medical staff. Other toasts were "The Right Hon. the Lord Ma and the Corporation of the City of London," proposed humorous vein by Lord Reading, the Lord Chief Justice, a responded to, in the unavoidable absence through acci of the Lord Mayor, by Alderman Sir Joseph Savory; "Th Honorary Medical Board," proposed by Lord Moult and replied to by Mr. John Morgan, C.V.O.; "The Chai man," given by the Bishop of London; and "The Mercha Taylors' Company," responded to by the Master, Mr. C. G Kekewich.

AT a meeting of delegates of the Devonpo Liberal Association, held on May 15th, Sir John Collie w adopted as the second Liberal candidate to contest t constituency at the next General Election.

METROPOLITAN HOSPITAL. — Sir Frederic Banbury, Bart., M.P., will preside at the annual festiv dinner, which will be held in aid of the funds of t Metropolitan Hospital on Friday, July 3rd, at the Whiteha Rooms, Hotel Metropole, London.

THE Bolingbroke lecture in connexion with th South-West London Medical Society will be delivered at t Bolingbroke Hospital, Wandsworth Common, on Wednesday June 10th, at 9 P.M., by Dr. W. Hale White, on the subje of Prognosis. All medical men are welcome.

CHELSEA CLINICAL SOCIETY. — The annua general meeting of this society will be held on Tuesday next, May 26th, at St. George's Hospital, in the club room of the Medical School, at 8.30 P.M. After the usual official business the President, Dr. T. B. Hyslop, will deliver a address on Self-control.

MEDICAL SOCIETY OF LONDON: LETTSOMIAN LECTURES, 1914.—The postponed Lettsomian lectures on Dysentery will be delivered by Dr. F. M. Sandwith at 9 P.M. on Tuesday, June 9th, Thursday, June 11th, and Thursday, June 18th. The second and third lectures will be illustrated by pictures and pathological specimens, mostly borrowed from the London School of Tropical Medicine.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.—In the report of this fund for 1913 an earnest appeal for financial help is made. Owing to the effects of strikes on the girls themselves who contribute to the fund, to the effects of heavy taxation on the generous public, and to the increase in railway charges, the useful work of the fund has been much curtailed. Subscriptions and donations should be sent to the honorary treasurer, 19, Norfolk-crescent, Hyde Park, S.W. The bankers are the London County and Westminster Bank, Holborn Circus Branch.

ROYAL INSTITUTE OF PUBLIC HEALTH: LECTURES ON INDUSTRIAL HYGIENE.—A course of lectures on industrial hygiene will be given at the institute by Sir Thomas Oliver, M.D., professor of medicine in the University of Durham College of Medicine, Newcastle-upon-Tyne, during the ensuing summer session on Wednesdays and Thursdays, at 4 o'clock. On May 27th the subject will be Factory Legislation; on May 28th, Injurious Occupations; on June 10th, Coal Mining; on June 11th, Gold Mining; on July 8th, Ankylostomiasis; and on July 9th, Dangerous Trades which have been Rendered comparatively Harmless. The fee for the course is 1 guinea.

ILFORD AND ITS LATE MEDICAL OFFICER OF HEALTH.—At the monthly meeting of the Loxford Ward of the Ilford Ratepayers' Association held on May 13th, Mr. C. F. Stovin, D.P.H. Lond., was presented with a gold watch inscribed as follows: "Presented to Dr. C. F. Stovin by members of the Loxford Ward of the I.R.A. and friends, 13th of May, 1914." Mr. W. H. Barnl[illegible], who presided and made the presentation, also read a manuscript address, signed by himself as chairman of the association, in which regret for the termination of Mr. Stovin's appointment was expressed. The address contained the following passage:—

> We entirely agree with the sentiment in the Local Govern[illegible] Board letter "that the medical officer of health has done nothing to merit discharge from his office," and we deplore the events that now deprive the ratepayers of Ilford of your wise and valuable experience in the administration of the Public Health Department.

Mrs. Stovin was presented with a bouquet of pink roses. Mr. Stovin having expressed his gratitude for the hon which had been done him and his wife, a number of speeches were made by members of the association and other ratepayers of Ilford expressive of approval of the work of their medical officer. Councillor Smith remarked that he had always found Mr. Stovin courteous and perfectly fair; Mr. Stovin's annual reports were a credit to the town, and the absolute loyalty, confidence, and respect of the whole of the public health and hospital staff to their medical officer spoke volumes.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Milk Bill.

THE text of the Milk Bill which Mr. HERBERT SAMUEL, the President of the Local Government Board, has introduced into the House of Commons has been issued. The right honourable gentleman briefly explained the scope of the measure at the time of the introduction.[1] As the measure is important the text of some of its principal provisions may be given.

Clause 1 prohibits the sale of tuberculous milk. It is in the following terms: "If a person (*a*) sells, or offers or exposes for sale, or suffers to be sold or offered or exposed for sale, for human consumption or for use in the manufacture of products for human consumption; or (*b*) uses or suffers to be used in the manufacture of products for human consumption; the milk of any cow which has to his knowledge given tuberculous milk, or which is suffering from emaciation due to tuberculosis, or from tuberculosis of the udder, or from acute inflammation of the udder, or from any disease liable to infect or contaminate the milk, he shall be guilty of an offence against this Act, unless he proves that he did not know and had no reason to suspect that the milk so sold or offered or exposed for sale or used was the milk of such a cow."

In Clause 2 an extension is proposed of the power to make orders respecting milk and dairies. It sets out that the purposes for which general and special orders with respect to milk and dairies may be made by the Local Government Board include: "(*a*) the registration with local authorities of dairies; (*b*) the inspection of dairies and persons employed in or about dairies; (*c*) the prevention of the sale for human consumption or for use in the manufacture of products for human consumption, of infected, contaminated, or dirty milk or the milk of a diseased cow; (*d*) the prohibition of the addition of colouring matter and the prohibition or regulation of the addition of skimmed or separated milk, or water, or any other substance, to milk intended for sale for human consumption, and the prohibition or regulation of the sale for human consumption of milk to which such an addition has been made; (*e*) the regulation of the cooling and conveyance of milk intended for sale for human consumption; (*f*) the labelling or marking of receptacles of milk for sale for human consumption and the identification of churns and vessels used for the conveyance of such milk."

When a medical officer of health of a county or a county borough is of opinion that tuberculosis is caused, or is likely to be caused, by the consumption of the milk supplied from any dairy within his area, he is provided with powers under Clause 3 and Schedule I. to report the matter to the county or county borough council. This authority, if in their opinion the dairyman has failed to show cause why an order should not be made, may make an order prohibiting him, either absolutely or unless such conditions as may be prescribed in the order are complied with, from supplying for human consumption, or using or supplying for use in the manufacture of products for human consumption, any milk from the dairy until the order has been withdrawn.

Clause 4 is important, and deals with the obligation to inspect dairies in certain cases. It is to the following effect:—"1. If the medical officer of health of any local authority has reason to suspect that tuberculosis is caused, or is likely to be caused, by the consumption of any milk which is being sold or exposed or kept for sale within the area of the local authority he shall endeavour to ascertain the source or sources of supply, and on ascertaining the facts shall forthwith give notice of them to the medical officer of health of the county or county borough in which the cows from which the milk is obtained are kept, whether the dairy where they are kept is within or without the area of the local authority, unless the local authority are themselves the council of that county or county borough. 2. On the receipt of such notice it shall be the duty of the medical officer of health of the county or county borough to cause the cattle in the dairy, and, where the case so requires, the persons employed therein, to be inspected, and to make such investigations as may be necessary. 3. Sufficient notice of the time of the inspection shall be previously given to the local authority whose medical officer of health gave the notice, to allow that officer or a veterinary inspector or other veterinary surgeon appointed by the authority being present at the inspection if the authority so desire. 4. The council of the county or county borough on whose medical officer of health the notice is served shall send to the medical officer of health of the local authority who gave the notice copies of any reports which may have been made by the medical officer of health making the inspection, and of any veterinary or bacteriological reports which may have been furnished to him, and shall give him information as to whether any action has been taken upon those reports and as to the nature of that action."

The Bill also deals with the power to take samples of milk, appointment of veterinary inspectors, regulations as to imported milk, establishment of milk depôts, enforcement of duties of local authorities, penalties, and application of the Bill to London.

Milk and Dairies (Scotland) Bill.

The Milk and Dairies (Scotland) Bill which Mr. MCKINNON WOOD, the Secretary for Scotland, recently introduced in the House of Commons has been printed. Its scope and aims are set forth in a memorandum. That memorandum states that the main objects of this Bill are to provide for—"1. The appointment by local authorities of a veterinary inspector. 2. The inspection of dairies and of the cattle therein. 3. The registration of dairies. 4. The provision of by-laws for—(*a*) the inspection of cattle; (*b*) the construction, &c., of dairies; (*c*) the prevention of impurities in milk and the cleanliness of persons engaged in dairy business; (*d*) the precautions to be taken by dairymen against infection. 5. The issue of regulations by the Local Government Board for Scotland for—(*a*) the prevention of danger to public health from the importation of milk, and (*b*) securing the supply of pure and wholesome milk. 6. The prohibition of the supply of milk which has caused or is likely to cause infectious disease. 7. The establishment by local authorities of milk depôts for the sale of milk specially prepared for infants. The provisions as to registration supersede the provisions as to the registration of dairies contained in the Contagious Diseases (Animals) Acts, and the orders made thereunder. The provisions as to the inspection of dairies and prohibition of the supply of milk are an extension of those contained in Sections 60 and 61 of the Public Health (Scotland) Act, 1897. The Board of Agriculture and Fisheries have issued an order under the Diseases of Animals Act, 1894, dealing with tuberculous cows, and providing for the payment of compensation in cases of slaughter. The Treasury are prepared, subject to the assent of Parliament, to sanction the payment from the Exchequer of one-half of the net amount paid by way of compensation for a period of five years."

Infants Milk Bill.

The Infants Milk Bill, introduced in the House of Commons by Mr. DOUGLAS HALL, is the third measure dealing with milk the text of which is published within a week. It is designed to secure the supply of pure milk to mothers of the poorest classes. It is a short measure.

Ireland and Public Health Grants.

It is now announced that the Government proposes to insert in the Finance Bill provisions which will make Ireland's share of the new money made available to local authorities by the Budget £697,500 for a full year. This money will be at the general disposal of the Irish Government and Parliament. This sum includes £67,500 for tuberculosis, nursing, and pathological laboratories.

Midwives (Scotland) Bill.

The Midwives (Scotland) Bill has been read a third time and passed in the House of Lords. On report an amendment was introduced recognising for the purpose of the Bill the qualification of midwives holding the certificate of the National Maternity Hospital, Dublin. This Bill has still to be considered by the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, MAY 13TH.

A Hospital Ship.

Mr. YERBURGH asked the First Lord of the Admiralty whether, in the Estimates for 1912-13, money was allocated for the provision of a hospital ship; whether such a ship was designed; whether the design was approved by the medical department; whether the construction of the ship had not been proceeded with; whether, in place of it, a merchant ship acquired by the Admiralty was being converted by them into a hospital ship; if so, what was the reason of this action on their part; and had it the approval of the medical department.—Mr. CHURCHILL replied: The facts are as stated in parts 1 to 5 of the question. As regards the sixth part of the question, I would refer the honourable member to the Admiralty letter to the Treasury printed on pages 103 to 104 of the Navy appropriation account for 1912–13. The arrangements for the purchase and conversion of the vessel have been drawn up in consultation with the medical department of the Admiralty throughout.

---

[1] THE LANCET, May 16th, 1914, p. 1423.

Insured Persons and Change of Residence.

Sir CLEMENT KINLOCH-COOKE asked the honourable Member for St. George's-in-the-East as representing the Insurance Commissioners what provision was made for change of doctor in the case where an insured person moved from one place to another; and, if notice was given on the day of removal, say from one part of London to another, how long a time should elapse before an insured person was given another doctor in his or her new domicile.—Mr. WEDGWOOD BENN answered: A fresh choice of doctor is exercised in the circumstances referred to by means of the medical card already in the insured person's possession. The card sets out clearly the steps to be taken by the insured person for this purpose and no delay need occur.

THURSDAY, MAY 14TH.

The Drug Fund.

Mr. GODFREY LOCKER-LAMPSON asked the honourable Member for St. George's-in-the-East whether a number of Insurance Committees were finding that the claims on their drug fund for chemists' accounts were growing in amount as compared with last year; whether such was the case with committees which had insufficient money to pay the chemists' accounts in full last year; and what the Government proposed to do to meet these increasing deficiencies.—Mr. WEDGWOOD BENN answered: Until the total sums available to each Insurance Committee have been finally ascertained and the accounts have been scrutinised the assumptions underlying the question cannot be accepted. In a few cases the Insurance Commissioners have received information that the accounts for the quarter which ended on the 11th of last month are in excess of those for the same quarter of last year, but no comparison between the amounts can properly be made until the accounts for each period have been examined.

Mr. G. LOCKER-LAMPSON asked the honourable gentleman whether the chemists under contract with the West Hartlepool Insurance Committee had had 30 per cent. deducted from their bills for last quarter, chiefly because the committee had insufficient funds to meet the bills; whether there was still outstanding and unpaid 10 per cent. of the chemists' bills for each quarter of last year; whether the number of prescriptions dispensed in that area had increased from 1800 in the quarter ending April, 1913, to 2200 in the corresponding quarter this year, and the cost increased from about £525 to £754; and whether the chemists and the Insurance Committee had expressed their dissatisfaction to the Commissioners.—Mr. WEDGWOOD BENN replied: The Insurance Commissioners hope to be able to inform the committee referred to at an early date of the total sum available to them from the drug fund for the past year. In the meantime, any payments made to the chemists are in the nature of advances only. For the reasons already explained in a reply to the honourable Member no comparison can properly be made at present between the accounts for last quarter and for the corresponding period of last year.

Institutional Treatment of Insured Persons.

Mr. GOULDING asked the Chancellor of the Exchequer whether, in addition to the proposals outlined in his speech in introducing the Budget, he would consider the possibility of placing adequate institutional treatment at the disposal of insured persons as part of their medical benefit.—Mr. WEDGWOOD BENN (on behalf of Mr. LLOYD GEORGE) answered: My right honourable friend will be glad to consider the honourable Member's suggestion, though I would remind him that the provision of grants in aid of the voluntary hospitals would necessarily raise the question of State control.

Institutional Treatment of Tuberculosis.

Replying to Mr. ASTOR, Mr. HERBERT SAMUEL wrote: 115 councils have submitted to the Local Government Board schemes for providing institutional treatment for persons suffering from tuberculosis, and in all these cases the scheme either expressly or by implication provides for the treatment of non-insured as well as insured persons. There are now six county councils and five county borough councils which have not yet submitted such schemes. In the case of one of these counties, the Isles of Scilly, no scheme is needed. In another (London) arrangements for providing institutional treatment for the non-insured as well as the insured population are now being developed. Of the county boroughs, two, Bournemouth and Grimsby, will, I have reason to believe, submit schemes at an early date.

Domiciliary Treatment of Uninsured Tuberculous Persons.

Mr. ASTOR asked the President of the Local Government Board whether the local authorities which undertook the treatment of uninsured persons suffering from tuberculosis within their district, with the aid of the Hobhouse grant, had power to provide for persons in receipt of domiciliary treatment the following among other articles of food—namely, milk, butter, eggs, bread, fish, and meat; and, if so, whether he would state what statute or statutes gave local authorities the power to make the above provision.—Mr. HERBERT LEWIS (on behalf of Mr. HERBERT SAMUEL) answered: My right honourable friend is in communication with the Treasury on this subject, and is not at present in a position to answer the question.

Grants for Expert Diagnosis.

Mr. CHARLES BATHURST asked the Chancellor of the Exchequer whether, in connexion with the proposed Government subsidy for the institution of pathological laboratories, he would consider the need of research work in connexion with contagious diseases, such as anthrax, tuberculosis, glanders, cow-pox, and foot-and-mouth disease, which were common to human beings and domestic animals, and apply a portion of the proposed grant towards the conduct of such research and the greater coöperation of the medical and veterinary professions in the interests of human health.—Mr. LLOYD GEORGE said in reply: The grants proposed are in respect of laboratories to be used primarily for purposes of expert diagnosis and not of research, but I understand that certain of the subjects mentioned by the honourable Member are engaging the attention of the Medical Research Committee.

MONDAY, MAY 18TH.

"Form Medical 32."

Mr. CHARLES BATHURST asked the honourable Member for St. George's-in-the-East why Form Medical 32 of the Insurance Commissioners was withdrawn; and whether, in view of the complaints consequent upon the inability of insured persons to obtain medical benefit owing to the difficulty of obtaining a medical card, the Commissioners would re-issue Form Medical 32, making it obtainable from such persons' approved society only.—Mr. WEDGWOOD BENN answered: The form referred to was part of the system which has now been superseded, and its adoption is incompatible with the present system. The form of application for a medical card which takes its place is obtainable at all post-offices, and no difficulty should be experienced by insured persons in securing a medical card on application.

BOOKS, ETC., *RECEIVED.*

ALLEN, GEORGE, London.
  Dr. Ivor's Wife. By Mary Kernahan (Mrs. Charles Harris). Price 6s. net.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DR. PETER CHAMBERLEN.

THE following advertisement appeared in the *Times* of May 16th, 1914:—

> "CHAMBERLEN. Any descendants of Dr. Peter Chamberlen, Royal Physician, of London (died 1683), would oblige by COMMUNICATING with C., Field House, Minchinhampton, Glos."

We do not know the object of this advertisement, but some details of Dr. Peter Chamberlen, quoted from Munk's Roll of the Royal College of Physicians, may not be familiar to all our readers. Peter Chamberlen was the son of Peter Chamberlen, a surgeon, who practised in the City of London. He was born on May 8th, 1601, was educated at Merchant Taylors' School, and graduated Doctor of Medicine at Padua in 1619 and at Cambridge in 1621. Dr. Chamberlen was admitted a candidate of the College of Physicians on July 6th, 1626, and a Fellow on April 7th, 1628. On Nov. 23rd, 1629, he was by a vote of the College dismissed from his Fellowship. His reputation must have been considerable, as the Czar wrote with his own hand a letter to Charles I., begging him to allow the doctor to enter his service. He was extensively engaged in the practice of midwifery, and attempted to obtain from the Crown authority to organise the female practitioners into a company with himself at their head as president and examiner. He purchased the Manor House of Woodham Mortimer Hall, near Malden, Essex, where a curious collection of midwifery instruments was discovered about 1815. He died on Dec. 22nd, 1683, and was buried at the Church of Woodham Mortimer. One of his sons erected a monument to his memory in this church, which stated that "The said Peter Chamberlen took ye degree of Doctor in Physick in severall universities, both at home and abroad, and lived such above three score years, being Physician in Ordinary to three kings and queens of England, viz., King James and Queen Anne, King Charles ye first and Queen Mary, King Charles ye Second and Queen Katherine, and also to some foreign princes, having travelled to most parts of Europe, and speaking most of the languages." He was a voluminous writer. Dr. Peter Chamberlen, senior, is more generally remembered as the inventor of the midwifery forceps, by the use of which he and his descendants acquired a great reputation as accoucheurs, keeping their secret to themselves for a long period of time.

"MILLIBARS."

To the Editor of THE LANCET.

SIR,—I am obliged to you for publishing my letter under the above heading in THE LANCET of May 16th. May I, however, correct an error in the third paragraph which escaped my notice when revising the proof. The "unit of acceleration" is the acceleration of 1 unit of velocity per second, or "1 centimetre per second per second," not, as it has been printed, "an acceleration of 1 centimetre per second."

I am, Sir, yours faithfully,
JOHN W. MOORE, M.D., D.Sc., F.R. Met. Soc.
Dublin, May 16th, 1914.

A MEDICAL MAN AND THE SPEED-LIMIT.

Mr. H. J. Bates was summoned recently at Evesham police-court for driving a motor-cycle at a speed dangerous to the public at Norton, and with failing to produce his licence. The evidence of a police constable was to the effect that the defendant drove at or about 40 miles per hour, and that he was stopped near a dangerous corner where several accidents had occurred. Other witnesses put the speed at 30 miles per hour. The defendant stated on oath that his pace was 20 miles per hour, and that he was fully aware of the dangerous corner which he was approaching. His evidence was corroborated by another medical man, Mr. H. H. Sampson, who was with him at the time, and a third medical practitioner, who had been riding in front of the defendant at or about 20 miles per hour, and had not been stopped by the police, corroborated with regard to the speed adopted. The magistrates dismissed the case, but fined the defendant 5s. and 8s. costs for failing to produce his licence. Mr. Bates is to be congratulated upon having successfully defended himself against a charge which involves the infliction of danger upon the public using the highway. Medical men may at any time be impelled by circumstances in which many would sympathise with them to break the law in order to reach a patient as quickly as possible, and for this reason it is very desirable that, being constant users of motor vehicles, they should earn the reputation of using them with consideration for others.

GRADUS AD OLYMPUM.

THE fact that one of the claimants to the Barony of Strabolgi, now in abeyance with the ancient Baronies of Burgh (1529) and Cobham of Kent (1313), is a medical man, Dr. Reginald Gervase Alexander, J.P., of Halifax and Bradford, naturally attracts attention to legal proceedings that would otherwise be devoid of medical interest. The circumstance that Dr. Alexander had his claim as a co-heir with one other claimant to the Baronies of Burgh and Cobham declared valid in 1912 by the Committee of Privileges of the House of Lords was the subject of an annotation in THE LANCET of August 10th, 1912. The same Committee has now further allowed the petition of three co-heirs, of whom Dr. Alexander is one, to the Barony of Strabolgi (1318), and will so advise His Majesty. The further development of the matter now rests with the King. Meanwhile, we congratulate Dr. Alexander on having been successful in getting the validity of his claims upheld in all three instances.

CONJOINED TWINS.

A NEW case of conjoined twins has occurred in America, and is reported in the February number of *American Medicine*. The mother is a white woman, aged 44; by a previous husband she has a son who is now 23 years of age, and quite normal. On Nov. 28th, 1913, she gave birth to two girl children, both a good deal below the normal standard of full term development; it is not stated what period of utero-gestation had been reached. They are united by a piece of tough fibrous tissue, about 4 inches thick and 12 inches in circumference, below the sternum, and reaching nearly down to the umbilicus. They have entirely separate thoracic and abdominal organs, except that the two peritoneal cavities are in communication through the band of union. Possibly it is due to this fact that a curious phenomenon occurs in respiration, for one twin inhales as the other exhales, and *vice versâ*. One child is very slightly larger than the other in most of its measurements, and appears stronger; this larger twin has a pulse rate of 130, whereas the smaller one's rate is but 120. The blood of the two children also exhibits differences. The larger child has 6,960,000 red corpuscles per c.mm. and 7500 leucocytes; the smaller one has 6,280,000 and 6335 respectively. The children are progressing favourably, and a photograph reproduced with the description shows them being fed, one from each breast.

MACAURA.

SOME of our readers may remember the proceedings of an American named Macaura who established institutes for the cure of various diseases by vibratory and other treatment a few years ago. We referred to the matter in our issue of Feb. 3rd, 1906, p. 347, and April 7th, 1906, p. 1014. In 1908 the proprietors of this journal took proceedings to restrain him from using the name of THE LANCET in a wrongful manner, as described in our issue of June 6th, 1908, p. 1673. It is now reported from Paris that Macaura was on May 14th sentenced to three years' imprisonment and to a fine of £120 for swindling, and that the medical societies who intervened were also awarded damages varying from £80 to £120. Other people who assisted Macaura in France were likewise sentenced to imprisonment and fine. The court set aside the charge of illegally practising medicine and convicted the accused of swindling.

◆

F. G. W.—Without knowing further details, such as age of patient, nature of malady, and possible susceptibility to the drug, it is difficult to give a definite answer; every third day would probably be a safe interval to begin with, but this method requires caution.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The Annual Oration

ON

THE SURGICAL TREATMENT OF INFANTILE PARALYSIS.

Delivered before the Medical Society of London on May 18th, 1914,

By ROBERT JONES, CH.M. LIVERP.,
F.R.C.S. IREL., F.R.C.S. EDIN.,

LECTURER ON ORTHOPÆDIC SURGERY AT THE UNIVERSITY OF LIVERPOOL.

MR. PRESIDENT AND GENTLEMEN,—When your Council graciously invited me to deliver the oration before this distinguished society I fear I had not the courage to refuse. The honour was such that for a time I did not realise my grave responsibility, and now I deplore the consciousness that I do not possess those gifts of erudition and imagination which have charmed while they enlightened you in the past. Despite the wide field you have allowed me, the choice of subject has not been easy. Devoted as my life has been to the more practical and clinical aspect of surgery, my horizon is for this very reason less comprehensive. I must, therefore, crave your kind indulgence while I deal in a simple and plain fashion with such principles as I have found helpful to me in dealing with infantile spinal paralysis. The subject is so vast and the technicalities are so manifold and intricate that I intend to dwell merely on those procedures which I have tested through the years and which have served me best, and to refer you to the work of others who labour in different ways in other fields. One must possess a buoyant spirit and boundless enthusiasm to treat these affections with advantage, and one must have fixed principles of wide application. If these principles are fundamental we must give them our whole-hearted allegiance and not merely pay them a transient homage. We can then afford to await results and not take heed of difficulties or yield to the counsels of despair. Like a mariner who meets an adverse wind we must not lack confidence, but exercise every art we know to land safely where we would.

There are few subjects which have aroused so much interest during recent years as that of infantile paralysis. This is due to its greater prevalence, its proved infectiveness, and the great advances in the method of attack which modern surgery has introduced. Unfortunately very little has been done in this country as compared with America and Germany by way of the collective investigation of etiological factors.

EARLY TREATMENT.

The early treatment of poliomyelitis falls of necessity into the hands of the medical man in attendance. It is on rare occasions only that the surgeon sees a case during the first few days, and then only where the onset of paralysis is accompanied by pain. Such cases are by no means rare, the pain being most marked in the spine and limbs. Rigid fixation of spine and limbs gives more relief than any other procedure I know. Indeed, I should make it a general rule that in every case, whether pain be present or not, the head and spinal column should be kept at rest in accordance with the general principles which guide us in the treatment of an inflamed area. The surgeon is often asked when treatment should be started. The answer is, "At once"; and during the acute and early convalescent stages the surgical treatment may be summed up in the word "rest," if this term be allowed to include the prevention of postural errors, such as tend to give an initial bias towards deformity.

Active treatment should commence *only* when the tender stage has passed. If a possibility exists that during the tender stage an active myelitis is present, there can be, in my opinion, no sound reason for the use of massage or electricity. How long may this tender stage last? I should say from three to eight weeks; in exceptional cases longer. We all know how difficult it may be to allay the parental apprehension during this period of surgical inactivity, but I have never found trouble when the reasons for the delay were made clear.

Our treatment should consist in placing the paralysed muscles in a position of relaxation, in the use of very gentle massage, and in active movements so conducted that no strain of the relaxed muscles be allowed. For instance, if the flexors of the ankle are being kept relaxed the foot should in no case be allowed into the position of equinus during massage, and any active movements should consist of flexion beyond but never below the right angle. Of this fact I have had many definite experiences. Some degree of voluntary muscular action should be encouraged as soon as possible, but at first there should be no movement of the joint, for the muscle is not strong enough to act against resistance. Thus, in a case in which the lower limb is fixed with the knee extended, in order to rest the quadriceps extensor, the first clinical sign of recovery will be a voluntary twitch of the muscle. The child's attention should be directed to this and he should be taught to practise it. The masseuse can soon lay a finger on the upper edge of the patella and so give a little added resistance. To allow the child to flex the knee at this stage would be to court disaster.

The character of the massage is very important and much harm may result if it be too vigorous. In this early stage it should consist of light vibratory effleurage applied as if to the skin, particularly over the area supplied by the same segments of the spinal cord as supply the impaired muscles. Rough kneading at any stage of the disease will damage fragile muscle fibre and diminish muscle tone.

POSSIBILITY OF RECOVERY OF MUSCLES.

Another question we are early called upon to decide is the possibility of recovery of weakened or paralysed muscle. This is often very difficult. It has always been the teaching that a muscle which exhibits the reaction of degeneration is outside the pale of hope, but years ago I drew attention to several instances where recovery took place in muscles where this reaction was carefully noted on the chart. This observation has been borne out and emphasised by many observers abroad. We may be certain that if a muscle reacts to faradism it will recover, but in actual practice the converse does not always hold. This may be due to the real difficulty that exists, sometimes even under anæsthesia, in making reliable observations in small children. The result is that in most active clinics complete electrical observations are rare. This would be a serious omission were no other means available to obtain trustworthy evidence sufficiently accurate to be a practical guide. We can, however, secure, with a little patience and gentle approach, much valuable information from general remarks, however, are necessary if my address is to be of practical use. Contracted knees and hips should be overcome slowly. It is highly injudicious to exercise much force; indeed, force in the form of redressment, apart from its dangers, is very inefficient. It is much easier to straighten the fixed limbs of arthritis by force than those of poliomyelitis. Division of tendons, fasciæ, and even ligaments may be freely performed. A tendon, however, which may at some future date be required for transplantation should be spared from tenotomy and be gradually stretched instead, for adhesions are very apt to form over old scar tissue.

A common deformity which is so often the despair of the surgeon of to-day is the one in which he finds both limbs contracted at the hips and knees, and where the spine is lordosed, the pelvis oblique, the knees in genu valgum, and the feet in equinovarus. My mode of attack in such a case would consist in the division of the tensor fasciæ femoris and of any other tight structures in that neighbourhood, moulding the feet into a valgoid position, dividing the Achilles tendons, and then laying the patient on a splint or frame of the Thomas's type, adding a simple extension to correct the pelvic obliquity, and with a bandage to the outside bars of the splint to overcome slowly the knock knees. The procedure is simple and invariably effective. The lordosis will usually be overcome in three or four weeks with barely any discomfort. We must employ gravity as our ally by so placing the limbs that time is not wasted. Even here common sense and practical experience must be of use. For instance, after division of the tensor fasciæ the limbs must be kept slightly hyperextended and rotated inwards, otherwise no strain is applied to tight structures. Where deformities are extreme, lordosis, no matter how pronounced, should be absolutely corrected if we are to attain the best functional result. Sufficient attention is hardly given to this very important point.

Many authors warn us to be careful of evils which may follow division of the Achilles tendon. The substitution of a calcaneus deformity for an equinus would be serious. This is a real danger in spastic cerebral paralysis, and a subcutaneous tenotomy in such a condition should never be performed. In my own experience, and I have divided the tendo Achillis and immediately corrected the deformity many thousands of times, non-union has resulted in three instances only. Despite this good fortune, in adults with extreme deformity, I generally employ one of the many methods of subcutaneous plastic division. The lengthening so much feared is the result of faulty after-treatment, the uniting tendon having been allowed to stretch before it is sufficiently strong to bear body weight. Another common mistake is to place a small pad over the site of puncture, so permanently separating one end of the tendon from the other. In a limb with three inches of shortening it is tempting to leave the tendon shortened and let the pa k
on tip-toe, but it is a temptation to be r r
we must always think of uscle gro
being stretched with le poten
recovery. If recov t take

securing nproved ction.

deformities may be overcome by manipulation, tenotomies, fixations, and extensions, and more rarely by osteotomies and the removal of bone. These preliminaries, however, are inevitable and allow of no exception. I emphasise this because I have frequently seen failure in tendon transplantations due solely to their neglect.

TENDON TRANSPLANTATION.

In briefly discussing the question of tendon transplantation I shall make no attempt to enter into the details of various operations, but will be content to point out what in my experience are the indications for its performance, the elements that make for success, and the causes of failure.

The object of a transplantation is to improve or restore muscular balance. It is not justified unless it improves function. There is little satisfaction to a patient if the transplanted muscle merely responds to faradism, or even makes a feeble movement by an effort of the will. It must be, or give the promise of becoming, a substitute for the muscle it supplants. It can only be judged by its usefulness. It may be applied to restore the balance between opposing groups of muscles by helping a redistribution of power, or its attachment may be slightly transposed to prevent deformity. Or it may be applied, as it often is, as an accessory to arthrodesis or in conjunction with the use of silk ligaments. Now, if we were to be guided entirely by the charts that have been worked out as to the relative strengths of muscles, and if we were to abide by them each time we desired to transplant a tendon, we should probably be discouraged at the very threshold. The tibialis anticus would be too strong to supplant the peronei, and the peronei too weak to act as a substitute for the tibial group. Although it is useful to possess the knowledge that the calf muscles are as strong as all the other muscles of the foot put together, we need not infer from this fact that in pes calcaneus no tendon transplantation need be tried. Healthy muscles can be developed to an extraordinary degree. Some years ago I was called upon to operate upon a boy whose peroneus longus slipped over his malleolus. This had happened for two years, and I was amazed at its great size. On inquiry I found that the dislocation, which was voluntary, was always accompanied by an audible snap, and the youngster collected pennies by displaying his gift and had thus greatly over-developed the muscle. Transplanted muscles by special exercise become similarly developed. The equalisation of forces, therefore, is not essential, for Nature has a large margin of adaptability, but for obvious reasons an effort should be made to get all the help possible when we have to secure substitutes for a powerful tendon.

Clearly the most important factor in commanding success is a sound judgment on the part of the operator. He should definitely realise what he wants to do and the means at his disposal. He should not be content merely to know the action of the muscle he is transplanting, but he should judge also of the disability he creates at the part from which the tendon is removed. There is no sense in substituting one deformity for another. Transplant are most successful when the
paralysis i and when re-enforcement can
be introdu close vicinity. The operator is
he best ju value and strength of tendons
his can l e by noting the active move
ents. le which responds to faradism

is not fit for transplantation. I have no sympathy at all with those surgeons who make large incisions to investigate the colour of the muscle fibre before they transplant. No operation should be done until evidence of sufficiently strong active movement in the muscle to be used has been obtained. Experience clearly indicates that we are justified in sacrificing abduction and adduction of the foot for plantar flexion and dorsiflexion, and that we can at any time sacrifice the mobility of the toes whenever the tendons are likely to be of use elsewhere. Paralysis of the calf muscles is the worst of all disabilities. I have long ago discarded complicated varieties of transplantation, the subdivision of muscles, and the many forms of fixation into tendons, and I rely more and more upon simple and direct methods.

For a varus deformity, I transplant the tibialis anticus; for a valgus, the peroneus longus and the extensor proprius hallucis. For a partial paralysis of the calf muscles, I shorten the tendo Achillis, pleat the posterior part of the capsule, fix the peroneus longus and flexor hallucis firmly into the insertion of the tendo Achillis, and remove an area of skin at the back of the ankle. Where the calf muscle is completely paralysed after correction of the cavus I transplant the peronei and flexor hallucis, with any other available muscle from the sole, into the tendo Achillis.

In cases where the paralysis is complete, or almost so, my own two stage bone wedge resection, or the operation of Whitman, which involves the removal of the astragalus and a readjustment of body weight upon the ankle, is sound and effective. In paralysis of the quadriceps I transplant one or more of the hamstrings, and these practically complete my list of transplantations except for rare conditions. I rarely utilise tendons in the upper limb, although occasionally I find it necessary in the spastic type such as infantile hemiplegia.

Technique Employed.

There has been much discussion as to the method of implantation. I am in no manner of doubt as to the great advantage of transplanting into bone. Lange and Vulpius respectively advocate grafting into periosteum and tendon, but when it is possible a graft into bone gives far greater security. There may be a sound reason on rare occasions for employing silk tendons, but I am quite satisfied that, wherever it is possible, the tendon should be directly implanted into bone.

If you will allow me I can best indicate the technique I employ by describing to you the operation of transforming the peroneus longus into an inverter of the foot. The tourniquet is applied above the knee and only removed when the wound is dressed and bandaged. This obviates bleeding, a source of danger to the security of the graft. An incision of about an inch in length is made on the outer side of the foot and the tendon is divided where it turns round the cuboid. A small incision is next made over the muscle, well above the external malleolus, and a smooth dissector is passed underneath the tendon, and it is pulled through the opening and wrapped in a sterile dab. A small incision is then made over or near the scaphoid, and a curved forceps is passed from this to the upper wound, preferably through fat, and moved about to make a free tunnel. The tip of the tendon is now held by the forceps and guided through the tunnel to its new insertion. Care must be taken that in its transit it runs as nearly as possible parallel to the tibialis anticus, and that there is no angle in any part of its course. The attachment may be made in one of two ways. A hole may be drilled through the scaphoid, or internal cuneiform, and the tendon passed through it. This is a method of choice. Or in a case where the tendon is short a groove may be made in the bone and the tendon may be made to lie in it while the end is fixed in ligamentous tissue below. The wounds are then closed and the foot is bandaged in inversion. No silk is used around the tendon which is secured by chromicised gut.

The important part of the technique is first and foremost never to handle the tendon with forceps anywhere excepting quite at its periphery, to pass it through fat, to secure the transplanted end in firm, unyielding tissue, and to see that the alignment makes for a direct pull. Experiments have conclusively shown that wherever a tendon is roughly handled adhesions form; for this reason it is well to compress the tendon with forceps at the point of its attachment—namely, at the end—but nowhere else. The causes of failure are largely due to errors of judgment and to faulty technique. This is suggested by the progressive improvement in our results. In many of my early cases the point of attachment yielded under the influence of strain, in others, adhesions formed. This was due to want of delicacy in the handling of the tendon, to the character of the structure through which it was made to pass, and to want of directness in the pull. The tunnel through which the tendon is directed should be roomy, the track through which it passes should be where possible in one plane, it should not pierce different layers, it should never abruptly turn a corner, nor perforate an interosseous membrane. The transplanted tendon should not be called upon to correct deformity, nor follow the convex aspect of a bone. It should not be allowed to travel immediately below the line of incision for fear of adhesions, nor be affixed to yielding structures. When its sheath can be preserved it is of advantage, but this cannot always be. Total transplantation is always preferable to partial, and when choice exists it is well to fix upon a muscle for transplantation whose function is similar to that which is paralysed. There is another point upon which I lay great stress, and that is an appreciation of the appropriate tension on the transplant. Under excessive tension muscle atrophies, while if the tendon is left too slack restoration of its function will be long delayed.

After the tendon is transplanted, and before education begins, a somewhat prolonged period of fixation is needed, all strain on the graft being prevented. Three months or more may be needed by the calf muscles; in the case of the everters and inverters of the ankle, from four to six weeks; the extensors of the knee require considerably longer. Light celluloid or leather splints of a removable kind may then hold the joint in position for an indefinite period, to prevent the harmful exercise of body weight during walking. The splints should be removed two or three times a day during the whole of this period for the practice of massage and active exercises under resistance. In other words, every care should be taken to strengthen the transplanted tendon for its new responsibilities.

Results of Tendon Transplantation.

Seven or eight years ago Hoffa, Lange, Vulpius, and I were invited to give our experiences of tendon transplantation at the French Congress of Surgeons in Paris. We differed from each other in our respective procedures, but we all spoke in favour of the operation. Our colleagues in France were not so enthusiastic, and Kirmisson especially drew attention to the fact that although immediate improvement occurred, it was generally followed by loss of function in the transplanted muscle. This has been referred to by many writers and must be within the experience of us all. Why should a muscle which is working at first fail later? With hardly an exception it is because we do not recognise in practice the principles in regard to muscle stretching which I have discussed at such length. Either the muscle has not been developed sufficiently to defend itself against an opponent, or, during walking, body weight has been allowed to bear injuriously upon it. These are both fundamental errors which are happily avoidable, and can, even when they have happened, be remedied by recourse to relaxation and massage.

I rarely operate upon children under 5 years of age for three reasons: First, because of the technical difficulty in handling and fixing minute tendons; secondly, because we should be sure that sufficient time has elapsed to give the muscles a chance of recovery without operation; and, thirdly, because it is most essential that the child should be sufficiently intelligent to give us help.

A fascinating problem to study is that of physiology or psychology as it affects the transplanted muscle. It is very difficult to understand how an inverter can be trained to evert the ankle, and how it can be made to exercise its new function by an effort of volition. Vulpius suggestively refers us to the work of Galen, Duchenne, and Sherrington on the function of opponent groups and draws attention to the well-known fact which we have all observed, that when we ask a paralytic whose extensors are lost to attempt extension of the toes he uses the flexors instead. This does not happen in a later stage. Both clinical and physiological investigations clearly prove that when a muscle or muscle group is stimulated to contract, the opponent muscle or group is inhibited. It has been argued, therefore, that a hamstring, transplanted into the patella to reinforce the quadriceps extensor, will not contract simultaneously with the latter muscle. According to this view, which is supported by Murk Jansen of Leyden, the only real benefit of this transplantation is that it makes the knee-joint steadier, and when the hamstrings contract in flexion the transplanted hamstring also contracts and prevents their uncontrolled action. Even if this were the whole truth of the case, the operation would be beneficial from the practical point of view, but it is not the whole truth; generally the transplanted tendon can be seen and felt to become tense simultaneously with the quadriceps extensor. In the present state of our knowledge I venture to suggest that this dissociation of the action of the transplanted muscle from its own natural group, and its association with a new strange group, is comparatively easily attained in children under careful muscle training. Certainly in adolescents a long and uncertain struggle between the opponent groups is often observed, suggesting that the older the patient the more difficult is education. In my opinion this indicates the necessity for more careful consideration of our methods of muscle training rather than a hasty condemnation of the operative procedure.

OPERATIONS TO GIVE STABILITY TO JOINTS.

Associated with the transplantation of tendons we have to consider measures which add to the stability of joints as distinct from their mobility; these consist of artificial ligaments, tendon fixation, and arthrodesis.

Artificial Ligaments.

As an outcome of the use of silk tendons by Lodge, several experienced surgeons are using silk ligaments in order to give stability to the joints and to guard newly transplanted tendons from strain. It is interesting to inquire what becomes of these silken tendons and ligaments. Anger and Gluck many years ago experimented upon the fate of silk strands used to fortify and bridge separated structures, and they concluded from experiments on animals that in some instances the silk was displaced by connective tissue, and in other instances the silk formed a trellis work along which connective tissue grew. Lange, who has had a very large experience, tells us that artificial silk tendons, with use, will develop from the size of a knitting needle to the thickness of a little finger. His microscopical examinations revealed the fact that the tissue immediately adjacent to the silk had all the characteristics of true tendon.

My personal experience, by no means an extensive one, has not been fortunate. I have operated upon only six cases. Each case healed uneventfully, but later in two instances the silk began to irritate at the points of insertion, and had to be removed. There was no attempt at the formation of connective tissue in either case, although the strands had remained quite aseptic. In a third case, many weeks after operation a suspicious reddening appeared over the knot, which had not been sufficiently hidden, and again the silk had to be removed. In two of the remaining cases the union was stretched, and in only one instance has the foot remained in a desirable position. All this may be due to faulty technique, but I am interested to note that Rich, of Tacoma, has had to remove the silk in 18 out of 40 cases in which it was used, although only in two cases was there any primary infection. Against these experiences I must refer to the successes reported by Lange, Tubby, Plummer, Ryerson, Allison, and others. In an interesting summary favourable to the use of artificial ligaments, Bradford and Soutter state in order to prove the strength and permanency of the ligament "that in a child of 8 the paralysed muscles largely recovered their function, and that in a man of 23 years, one year after the operation, not only was a foot-drop prevented, but some restoration of function furnished." This is only a further confirmation of the advantage of preventing strain from falling upon so-called paralysed muscles. We should keep a very open mind upon this question. The fixation of artificial ligaments into bone is so simple, and offers so many inducements, that if we can feel assured by further experience that the silk will not give rise to trouble, the method will have an assured position. For instance, in foot-drop with complete paralysis of the anterior muscles, if the silk will not merely remain, but will also develop in thickness and strength, a distinct gain will be conferred. Even when the paralysis is not complete it may prove, as in the cases reported by Bradford and Soutter, an effective means for protecting the over-stretched muscles.

Tendon Fixation.

At present the operation of utilising the tendons as ligaments has a greater fascination for me. Tilanus first suggested it and it is capable of very general application. It involves sacrificing the tendon, so it becomes obligatory to make quite sure that the paralysis is permanent and complete. If the tibials are paralysed, for instance, an incision is made above the ankle and the tendon of the tibialis anticus is pulled upon until the eversion of the foot is corrected. It is then securely fixed under the necessary tension into the periosteum or bone. The tendon may be divided, but often it is quite unnecessary. The deformities of equinus and varus are overcome by similar procedures. This operation seems to me to be more physiological than is that of the introduction of silken cords, for we are using a homogeneous tissue which will not act as a foreign body.

In the present stage of our knowledge, operations such as I have described are insufficient when we have to deal with a flail joint, over which there is no muscular control, if it has to support body weight. With further and improved methods of using tendon fixations and artificial ligaments, both within and without the joint, we may in time be able to make such joints capable of bearing the strain of walking; at present, however, this is not so. Tendon transplantation, unassisted, is of very little use at the ankle where several of the muscular groups are totally paralysed. Lange speaks optimistically of producing useful function at the ankle-joint if only three muscles are left to him. Under such circumstances he would use two for dorsiflexion and the third as a substitute for the Achillis tendon. I am sorry to say, with so limited a choice, I should be hopeless of success. There is no single muscle which can undertake the duties of the tendo Achillis. When we have a flail ankle to deal with the only operative success at present is arthrodesis.

Arthrodesis.

Over 20 years ago I advocated the bony fixation of flail joints in the position of greater advantage. At that period the operation had only on rare occasions been performed. I fear that my enthusiasm carried others as well as me into a somewhat too confident generalisation as to its merits and indications. There was then no choice of methods. It predated plastic work. There is nothing I regret more than that in those days I argued in favour of arthrodesis of the knee in childhood. It is an operation which a more matured experience teaches me should never be performed upon a child. In the *adult* it gives an admirably firm limb, and under certain conditions it may prove the best thing to be done. There are many who are very grateful to be spared the use of troublesome apparatus. There are others who have come to me whose knees were stiffened in childhood and who beg for a restoration of motion. A surgeon can have no experience more bitter. No knee-joint should be fixed until the patient is old enough to appreciate fully the arguments in favour of, and against, the operation. In the child it often results in a pseudo-arthrosis; sometimes it develops into a bony flexion, and it is very apt to throw harmful strain upon the hip, the muscles of which so often participate in the paralysis. Even in the adult, if the facts are clearly driven home to the patient, his choice will fall often upon some form of cheap and light support whereby he may be less awkward than if his limb were stiff. I am prepared to admit that certain people with blue dangling limb, retaining some power in the psoas muscle, may find ankylosis of knee and ankle combined a real boon.

Arthrodesis of the ankle-joint is quite another matter and is often of very considerable advantage. It should be usually associated with fixation at the mid-tarsal joint, should never be performed upon a child under 8, and it is better to delay even longer. Vulpius disagrees with me upon this point, but his arguments do not appear to be in the least convincing. The delay renders ankylosis much more certain, and with ordinary care the deformities and contractures he speaks of will not occur. The deformity which sometimes occurs after this operation is an obstinate varus and is due to a faulty technique. Before the operation, if there is any cavus deformity, the sole should be flattened and all tight structures severed. After its completion the bare surfaces of the astragalus should be closely hugged by the malleoli, while the foot should be fixed with flattened sole in a position of slight abduction. This position should be maintained for at least four months. The hip and wrist should never be ankylosed, nor do I see any advantage in operating upon the elbow. The shoulder requires a bony fixation where the deltoid only is paralysed and the scapular muscles are active. The humerus should then be abducted, drawn forward, and slightly rotated inwards, when it will respond at a useful angle to movements conveyed through the scapula.

We must remember that, at the best, arthrodesis is a mutilating operation and should be the last resort. If a mistake is made it cannot be remedied, and mistakes unfortunately are frequently made. Some time ago I saw a boy, aged 10, whose knee had been arthrodesed because of paralysis of the quadriceps extensor. The paralysis had lasted three years before the operation was performed. As an arthrodesis, the result had been a failure, because the knees moved, but the profoundly interesting fact is to come. The quadriceps, so long rested, had recovered, and the knee could be easily and strongly extended. It was a valuable object lesson to all who saw it.

NERVE SUTURE.

We have discussed the various methods by which we are able to give immense relief to these crippled children. We can generally avoid deformity; we can always correct it. We can often rectify lost function and make flail limbs firm. Such results are very important, but it would be depressing to feel that we are destined always to travel on these lines: building up by complex mechanism, steel splints without, silk splints within, muscles fixed to new attachments, and joints ruthlessly destroyed. Our thoughts naturally turn to more conservative methods by the way of the nervous system. Whether nerve-crossing is ultimately to lead to great triumph or to bitter disappointment we cannot yet answer without being biased either by hope or despair.

The many successful cases of nerve suture in man which followed that of Baunders in 1835 have placed this operation upon a sure foundation, and primary suture is to-day a daily routine. Similarly, secondary suture has outlived its experimental stage and under favourable conditions we can predict success. From this it does not seem a wide step to nerve-crossing, and yet it is a momentous one. Perhaps the earliest success was reported by Sick and Sanger, who grafted a portion of the median nerve into the radial. In our own country, in 1895, Ballance met with gratifying success when he united the facial to the spinal accessory. The physiological theory of the neurones was adverse to the experiment, but, as sometimes occurs, the findings of the more exact sciences are modified by the findings of surgical empiricism. The work of Ballance and Stewart was founded on the belief that regeneration occurs in two ways—by a downward growth of axis-cylinders from the proximal or central segment, and by essential processes of regeneration in the distal end in the form of a new growth of neurilemma cells, which become part of the new axis-cylinder.

I believe the present position of the neurologist is once more the old one—that the axis-cylinder grows down from the proximal end, but the neurilemma cells play an important part in its nutrition and assist its downward growth. Should the distal segment not be sutured or bridged, the impulses to and from the central nervous system cannot travel, and these new parts therefore never become developed, but merely exist as embryonic nerve structures. As Osgood has suggested: "In the problem which presents itself in cases of paralysis following acute poliomyelitis we find different conditions existing from those obtaining in traumatic or experimental division of nerves, and questions demanding answer at once arise. How essential, if true, is this process of regeneration in the distal or peripheral segment to future conductivity and *restoration of full function.* Are the nerve trunks, which run to the paralysed muscles, themselves affected by the disease we are considering, and if so does regeneration occur in the trunks as the *infectious process subsides? If it does not,* must we consider this degenerated old nerve trunk as simply a scaffolding, or bridge, and suppose that the new axis-cylinders of motion, growing from any healthy proximal or central trunk into which the diseased nerve may be grafted, must travel along such a path before we may expect any return of motor power?" These are certainly interesting questions when we compare the almost brilliant results of experiments on animals and the excellent results obtained after primary and secondary suture in man with the hitherto distinctly disappointing results obtained in infantile paralysis. There is no evidence that the virus of poliomyelitis attacks the peripheral nerves. In comparing results of operations on cases of paralysis with those of nerve-crossing after experimental section, we must remember that in the former we are dealing with nerve trunks which have for a long time been in a state of disuse.

Every now and again a partially successful case is reported. Spitzy, who has been one of the most assiduous workers in this field, has obtained encouraging results. Partially successful cases have been reported in our country by Tubby and by Sherren, and we have now in literature records of over 50 cases. Warrington and Murray, in a very able and useful communication, report five failures after most carefully conducted operations. The authors suggest that a cause of failure may be the fact that the apparently healthy nerve trunks, which conduct energy to the paralysed muscle, are less virile and can draw from fewer motor cells than before the disease; while they may just have enough to supply their own trunk they have none to spare for another.

Topography of Cross Sections of Nerves.

Quite recently a new impetus has been given to this subject by the investigations of Stoffel, who, by an elaborate system of dissection, has worked out the topography of the *cross* section of nerves. He seems to have proved conclusively by very laborious dissections that the nerve branch to each muscle is continued for a considerable distance up the nerve *trunk* as a separate and distinct nerve bundle. He maintains it to be fairly constant and definite in position, and by a study of the nerve any bundle desired at an operation may be secured. Nerve *graftings* should be materially helped by this discovery, as healthy nerve tracts which *go to* supply muscles of minor importance can be drafted for implantation into paralysed nerves. Without this knowledge motor fibres might easily be attached to sensory ones. This is contrary to *the previous* findings of Bruandet, whose experiments led him to conclude that the motor fibres in a peripheral nerve have no compact distribution, but are diffused and mixed up with all other fibres. If Stoffel's conclusions are correct, our technique will be much simplified. It is obvious that if one attempts to cure a paralysis of the extensor group of muscles in the leg *by splitting off* a strip of the internal popliteal nerve and planting it into the external popliteal, there is no reason why the graft should not unite—modern surgery can secure that. Further, as we have seen, our modern knowledge of the regeneration of nerves gives us every assurance that the graft ought to perform its function in conducting nerve impulses provided the *portion split off* is a bundle of motor fibres, and provided it is planted into the proper bundle of motor fibres in the other nerve and not into a portion of it which contains only sensory fibres. This is the practical anatomical difficulty which up to now has remained unsurmountable. When we turn next to the successful cases, which have been *reported,* some are *probably* cases in which the surgeon has really succeeded in grafting motor fibres into motor fibres. When, however, we look up the details of after-treatment, in several instances we find that part of the treatment consists in *fixing* the limb in a position in which the paralysed muscles are relaxed, so that they may more readily respond to any impulses sent down *through* the regenerated nerve. Here, in my *opinion,* lies the fallacy, for some of these cases might have recovered, if fixed in this position for a sufficient period, without transplantation. In support of this Wittek, of Gratz, *knowing my views* upon this subject, sent me a report of one of his cases. It was sent on from the neurological department with a *report of* reaction of degeneration in muscles *supplied by* the external *popliteal* nerve. Relying on this report he performed muscle transplantation, and the result was successful. A year later the *patient came back* with an extreme valgus, *the* internal malleolus touching the floor. On examination the muscles previously pronounced to be hopelessly paralysed were now acting strongly, *while* the previously strong groups were *paralysed* from overstretching. There was nothing for it but to reverse his former operation and put his transplanted muscle back where he found it. His remark was, "What a *brilliant result to record* if I had only done nerve transplantation." Many of us have had similar experiences in cases where we have *been hasty* in transplanting muscles.

Although the results of neuroplasty in poliomyelitis leave much to be desired, there is *no* occasion to abandon hope. We may *learn in time* the lessons *taught by failure,* and, what is infinitely more important, take courage from success. A failure depresses, but a success is eloquent of possibilities, and that is just the encouragement we want. Failure should merely set us thinking, and however critical our mind it should always remain an open one.

INTRINSIC CANCER OF THE LARYNX:

COMPLETE EXCISION APPARENTLY EFFECTED BY ENDOLARYNGEAL OPERATION.[1]

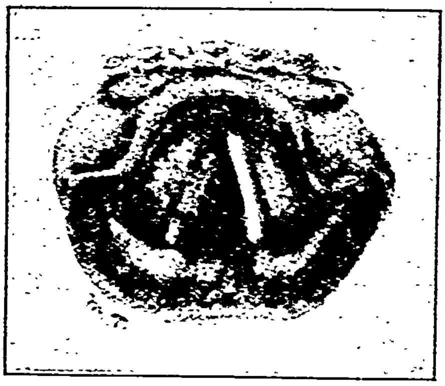
BY SIR STCLAIR THOMSON, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,
PROFESSOR OF LARYNGOLOGY AND PHYSICIAN FOR DISEASES OF THE THROAT IN KING'S COLLEGE HOSPITAL.

THE treatment of intrinsic cancer of the larynx by laryngo-fissure is remarkably satisfactory. It is doubtful if the results of operation for cancer in any other part of the body can surpass those I have already published.[2] Since giving full particulars and showing cases before the Medical Society of London in 1912 I have continued to obtain the same results—i.e., no patient has been lost by operation, and 80 per cent. have remained free from recurrence. This freedom from recurrence dates back in some cases for 10 years. The same proportion of lasting cures was obtained by Semon, who did so much to popularise laryngo-fissure in these cases, and similar records were secured by Butlin, who revived the operation after it had been quite discredited both in this country and abroad. Possibly it is because these excellent results were first obtained in England that we in this country have come to look askance at any other route for removing an endolaryngeal cancer except that obtained by splitting the larynx. We are even a little sceptical in accepting the records which claim permanent cures by operating through the mouth, yet such cases have been published by several eminent authorities.[3]

Amongst my recent cases it has been my good fortune to obtain, in a curious way, the definite proof that an intrinsic cancer of the larynx can be completely removed *per vias naturales*. But I hasten to add that the completeness of removal was unintentional, and that I do not for a single moment suggest that excision of a cancer of a vocal cord should ever be confided to the laryngeal forceps. On the contrary, this very case which I am about to relate gives the strongest proof of the desirability and hopefulness of treating intrinsic laryngeal cancer by opening the larynx from the outside. It was the first case of endolaryngeal cancer which I have handled in a woman; all my other cases were males.

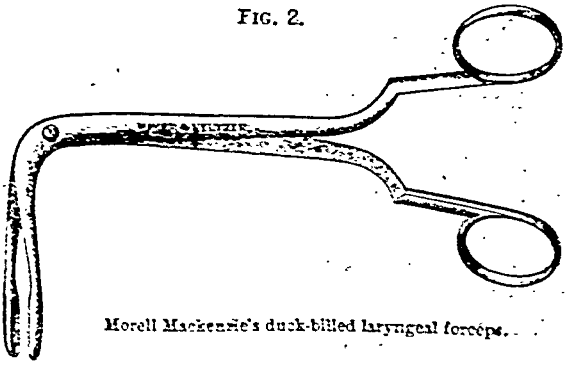
The patient, a woman aged 53, had been hoarse for eight months, when she was sent to me at King's College Hospital on Oct. 12th, 1912, by Dr. R. H. Shaw, of Great Yarmouth. The right vocal cord from the anterior commissure back to the vocal process was replaced by a reddish, cauliflower growth. (Fig. 1.) This somewhat interfered with the movement of the cord, but its intrinsic mobility was not impaired. There were no enlarged glands, and the case was evidently a very suitable one for operation by laryngo-fissure. The Wassermann reaction was negative and the chest was healthy As the growth did not infiltrate the cord to any great extent (as shown by the persistence of mobility), and as it projected well above the surface, I decided to remove a portion so as to confirm the diagnosis by microscopical examination. With the aid of cocaine, and using a large-sized duck-billed forceps of Morell Mackenzie (Fig. 2) with the indirect method, I seized as large a piece of the cord as possible, and, finding it very tough, I removed it by avulsion. The toughness and naked-eye appearance were confirmatory of my diagnosis of malignant disease, and the following report on the removed tissue was kindly furnished by Dr. W. d'Este Emery:—

FIG. 1.



Malignant growth of right vocal cord.

FIG. 2.



Morell Mackenzie's duck-billed laryngeal forceps.

> The material is an irregular mass about 9 × 5 millimetres. It is divided into two parts, of which one consists of papillomatous and epitheliomatous tissue, with a very small amount of fibrous stroma which shows evidence of subacute inflammatory changes. The large portion consists of a firm fibrous basis. On one edge there are some mucous glands. On the other two unattached edges there is a margin of epitheliomatous tissue, which in places is inflamed and ulcerated. The epithelioma in this section is a typical one, but shows little keratinisation. There are a few imperfectly formed cell nests, and some so-called "cancer parasites."

On Nov. 28th, 1912, anæsthesia was induced by intravenous infusion of ether and hedonal. The usual laryngo-fissure operation was carried out; no Hahn's tube was used. The remains of the right cord and the ventricular band were dissected up with their perichondrium from the inner surface of the thyroid cartilage and removed *en masse*, together with the vocal process of the arytenoid cartilage. The tracheotomy tube was removed before the patient left the table. The patient would have been allowed up the next day, but she was exceedingly drowsy from the hedonal and could hardly be roused. However, within 48 hours of the operation she was sitting out of bed and taking solid food. She returned to the country a fortnight after operation.[4]

[3] B. Fraenkel: Deutsche Medicinische Wochenschrift, xx., [illegible], Nos. 1 to 6, S. 1 to [illegible]; Archiv für Laryngologie, vi., [illegible], S. [illegible] to [illegible]. Arslan: Archivii Italiani di Otologia, [illegible], fasc. 2; Annales des maladies de l'Oreille, xxx., 1, Fev. 1904, p. [illegible]. (Gives an analysis of [illegible] cases. Two personal cases, confirmed by the microscope, [illegible] well after 4 years and 20 months respectively.) Fetter: Journal of Laryngology, vol. xxv., 1910, No. 11, p. [illegible].

The tissue removed by laryngo-fissure was submitted to Dr. Emery, who reported on it as follows:—

> The specimen is of an irregular shape, the longest dimensions being 19 × 10 millimetres. The base consists of striped muscle which is inflamed and œdematous; some mucous glands occur in the lowest portion. Above this there is a layer of organising granulation tissue in various stages, but there is no epithelial covering. Mucous glands, normal or slightly inflamed, are scattered throughout the section, and at one end there is a triangular piece of cartilage about 2½ millimetres long. There is no sign of epithelioma or other malignant disease in any other part of the section.

This report brings us to the instructive conclusions which may be drawn from this case, and, to be brief, I will simply state them in order.

1. Cancer of the vocal cords is, in early stages, a very slowly progressive and strictly limited process. (N.B.—In this case hoarseness dated from eight months, the cord was still quite mobile, and the disease was still superficial.) Alteration of voice is the principal, and may be the only, symptom. Persistent hoarseness in any patient calls for a definite diagnosis.

2. Diagnosis is based chiefly on inspection of the larynx. Only in certain cases, where the growth is a superficial and not an infiltrating one, can it be confirmed by microscopical examination.

3. The growth, even when it occupies almost the entire length of a vocal cord, can sometimes be completely removed by endolaryngeal operation in early cases. But this completeness can only be ascertained when, by laryngo-fissure, the remains of the vocal cord and adjoining soft parts have been removed and submitted to the pathologist.

4. Laryngo-fissure is, therefore, the operation of choice in all cases of endolaryngeal cancer.

5. The operation offers the very best prospects: first, because the disease remains for some time superficial and limited; and secondly, because laryngo-fissure cannot be considered a dangerous operation.

6. Statistical results show a lasting cure in 80 per cent. of cases, and if all cases presented themselves and were diagnosed early there is no reason why the results should not be even more satisfactory.

My patient is in good health, with a useful voice, and has no recurrence at the present date—that is, one and a half years after operation.

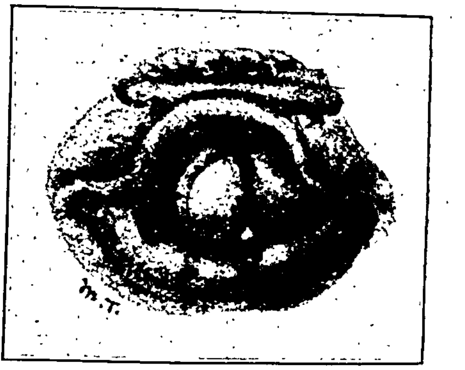
I have already confirmed the opinion originally enunciated by Semon, that if recurrence does not take place during the first year after operation there is every prospect of permanent cure.

ADDENDA.

In addition to the six conclusions I have tabulated above this case suggests three other points which, I think, are very interesting:—

(*a*) *Regrowth.*—Towards the end of January, 1913—i.e., two months after operation—the patient began to show symptoms of what many would have taken to be a recurrence of the growth. (Fig. 3.) But I had no anxiety myself, partly on account of the above negative report from the pathologist, but chiefly from experience with previous cases in which a regrowth during the first two months nearly always proved to be a simple granuloma. In this case the fresh neoplasm was removed entire through the mouth, with the same Mackenzie forceps and by indirect laryngoscopy, and was found to consist of simple granulation tissue, showing no epithelioma or sign of malignant disease in any part of the section. The moral of this is that a regrowth, in early days, after a thyrotomy for cancer is not necessarily malignant.

FIG. 3.



Granuloma following removal of malignant growth of right vocal cord.

(*b*) *Value of indirect laryngoscopy.*—The case shows that a considerable growth, indeed, practically an entire vocal cord, can be removed with one bite of the forceps used by the indirect, or, as some already call it, the "old method" of laryngoscopy. As I have practised Killian's direct laryngoscopy for 11 years I feel equally skilled with both methods and each method has its own well-marked indications. I very much doubt if the most expert endoscopist could have removed as large a growth as I did in this case, and certainly it could not have been done more quickly or less disagreeably. The indirect method allows of the forceps being sloped to the opposite side of the body, so that any growth on a cord can be more cleanly and completely seized than is possible with the limited action of cutting forceps working in a circumscribed circular tube. The importance of removing as large and intact a portion of growth as is possible is of the highest value when it is desirable to submit a suspected neoplasm to the microscope. It will be a loss to laryngoscopy, and to our patients, if the rising generation of throat surgeons neglects to acquire the gentler art of indirect laryngoscopy and limit themselves to the easier but rougher technique of direct examination.

(*c*) *Anæsthesia.*—Laryngo-fissure can be well carried out under local anæsthesia. I have employed it in one successful case, but I doubt if many of our sensitive patients in this country would submit to the moral ordeal. In the above case the operation lasted 85 minutes. Anæsthesia was induced by a mixture of 1 ounce of ether and 20 grains of hedonal to a pint of normal saline solution, the object of the hedonal being to diminish as far as possible the total amount of fluid passed into the circulation. Two pints and six ounces of this mixture were used corresponding to 2 oz. 2½ drm. of ether and

---

[4] The patient was shown before the Clinical Section of the Royal Society of Medicine on Feb. 14th, 1913.

46 grains of hedonal, including a certain amount of wastage. Probably 2 oz. of ether and 40 grains of hedonal were infused through the internal malleolal vein, just above the ankle. As administered by Dr. J. F. W. Silk the resulting anæsthesia was, from the operator's point of view, ideal. The field of operation was quite clear of the anæsthetist and his paraphernalia, and the patient's sleep was tranquil and even. But the profound sleep in which she continued to be plunged next day gave me some anxiety. For 24 hours it was difficult to rouse her, and I thought what a serious condition might have arisen if, peradventure, she had inspired any blood during the operation and we had wished her to cough up the resulting bronchial or pulmonary catarrh. I would suggest that in future cases the hedonal be reduced to a minimum, if it cannot be dispensed with.

In another case I had there was some thrombosis of the lower part of the internal saphena vein, and this kept the patient in bed when he ought to have been up and about. Besides, I am not quite sure whether it is wise to flood the circulation with over two pints of liquid, and it is difficult to keep within this limit unless some such drug as hedonal be employed with its corresponding tendency to prolonged and profound after-sleep. Anyhow, the method of anæsthesia by intravenous infusion of ether has not yet established itself, in my opinion, for these cases and it still requires consideration. In my more recent cases I have returned with satisfaction to the use of chloroform employed in the usual way.

Wimpole-street, W.

A NOTE ON

A METHOD BY WHICH REMEDIAL AGENTS MAY BE MINGLED WITH THE CEREBRAL CEREBRO-SPINAL FLUID.

BY CHARLES A. BALLANCE, M.V.O., M.S. LOND., F.R.C.S. ENG.,

SURGEON TO ST. THOMAS'S HOSPITAL AND TO THE WEST END HOSPITAL FOR NERVOUS DISEASES, ETC.

SOME time ago Dr. Harry Campbell asked me to introduce salvarsanised serum into the cranial cavity in such a way as would admit of the serum coming in contact with the brain cells the life of which was in danger from the syphilitic virus. The consideration of this suggestion naturally led the mind along two lines of thought: (1) the argument for this plan of treatment, and (2) the best method to adopt for the purpose in view.

I.—*The Argument.*

There is a general belief that while anti-syphilitic remedies are useful in the gross lesions of meningeal syphilis, they are quite ineffective in the lesions of parenchymatous cerebral and spinal syphilis. There is some evidence that the injection of salvarsanised serum into the subarachnoid space of the spinal theca has been followed by improvement in the signs and symptoms of certain early cases of spinal syphilis. It is also fairly certain that the injection of the serum into the spinal theca is less efficacious in the lesions and symptoms of cerebral syphilis than it is in the early stages of spinal syphilis. The question therefore arises whether benefit would follow the introduction of salvarsanised serum into the subarachnoid spaces of the brain. Is it not fair to conclude from a comparison with the results obtained by the injection of the serum into the subarachnoid spaces of the spinal theca that the answer to the question may be in the affirmative?

In all the great emergencies of surgery early diagnosis alone can lead to early and successful operation. No emergency can be more urgent than that which has for its object the saving of the life of nerve cells. The method proposed therefore can only be effectual in the very earliest stage of cerebral disease, that is, before extensive damage has been done to the brain cells. The preclinical stage of cerebral disease is therefore the ideal time for the commencement of treatment. In these earliest cases repeated injections may possibly be necessary. How, then, can salvarsanised serum be introduced into the cerebral subarachnoid space so that it may mingle with the cerebral cerebro-spinal fluid and destroy the spirochæte which is threatening the life of the brain cells?

Key and Retzius in their classical work published in 1875 showed that the subdural and subarachnoid spaces of the brain of man did not communicate except in the Pacchionian bodies which are found in relation with the superior longitudinal, the lateral, and the straight sinuses. The simultaneous injection of the subdural and subarachnoid spaces by differently coloured fluids was successfully carried out, and the only places where they mingled was in the Pacchionian bodies. If the injections were continued the coloured fluids made their way into the lumina of the venous sinuses. It would seem, then, that salvarsanised serum to be effective must be introduced not into the subdural but into the subarachnoid space, because it is within this space that the brain and its cells are placed. The cerebro-spinal fluid bathes and nourishes the brain cells. Is it not fair to hope, then, that the integrity of the brain cells in cerebral syphilis may be maintained if salvarsanised serum is mixed with the cerebral cerebro-spinal fluid?

The anatomical injections of Key and Retzius have a great and permanent value. The experiments of Dr. Golla on the distribution of colloidal carbon when injected under the cerebral or spinal dura mater of the living animal are of surpassing interest. They strike a new note in the living anatomy and pathology of the nervous system, and may open a new path for the treatment of cerebral and spinal disease. For long years neurology has been living more or less in the stage of "dead meat" pathology. This period was reached in general pathology when I first entered the profession, for then the members of the Pathological Society of London were solely engaged in showing at their meetings specimens of disease obtained from the post-mortem room and microscopical specimens of the same. What is now urgently required is a great scheme for the endowment of research into the living pathology of neurological disease—for the quest of the intimate causes, living and chemical, of the diseases of the nervous system.

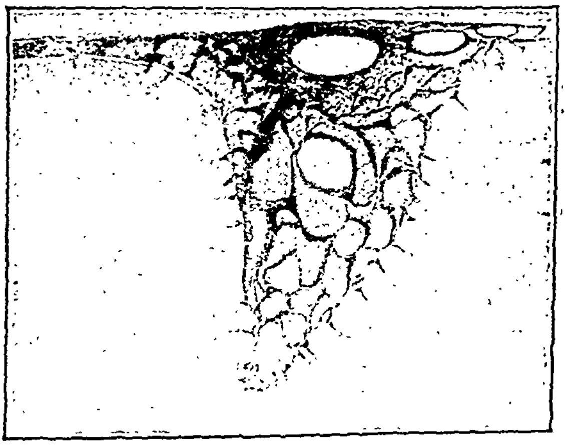
The arachnoid membrane in man is a very definite membrane. It consists of riband-like bundles of fine fibrous tissue interlaced with one another. The intervals between these bundles are filled up by delicate membranes. Several layers of this tissue, arranged in a complex way, constitute the arachnoid proper (Quain's Anatomy). The trabeculæ and membranes which cross the subarachnoid space consist of similar fine fibrillar tissue, and are continuous with the intertrabecular cell membranes of the arachnoid itself. When I introduced 6 c.c. of salvarsanised serum into the subdural space, it only remained there when the tube and glass vessel were raised to a considerable height. On lowering the glass vessel the serum returned into it. The glass vessel was again raised and the serum caused to return into the subdural space. The fine hollow needle was then withdrawn and from the puncture in the dura caused by the needle the serum spurted out under pressure.

When the arachnoid membrane is dissected off the convolutions and arranged so as to form a vessel it holds water without a leakage. Though in the living state diffusion of fluid may occur in man through the arachnoid membrane, there is obviously no gross opening between subdural and subarachnoid spaces.

The amount of cerebro-spinal fluid normally present has been estimated at from 120 to 200 grammes (Testut). It is found in the ventricles, in the cisterns at the base of the brain, and in the brain tissue itself. The brain, like a sponge, holds in its tissue much cerebro-spinal fluid. In the practice of surgery displacement of certain regions of the brain by gentle continuous pressure is a common event. This displacement is effected by displacement of the fluid which is normally contained in the substance of the brain. The specific gravity of the brain substance (1030) is not greatly in excess of that of water, and on its "liquid texture" depends, in some measure at any rate, the hope of success in the treatment of cerebral disease by the introduction of remedial agents into the cerebro-spinal fluid.

The arachnoid membrane passes from convolution to convolution. The spaces or sulci between the convolutions are part of the subarachnoid space. The subarachnoid space of each sulcus is broken up into a number of channels (Fig. 1), through which the cerebro-spinal fluid finds its way. These subarachnoid rivulets are continuous with the sheaths of the pial arteries which supply the cortex with blood.

FIG. 1.



The subarachnoid space in man between the convolutions. The space is here broken up into a number of channels through which the cerebro-spinal fluid finds its way. Some of the sheaths of the pial arteries are shown perforating the cortex. The fluid of the subarachnoid rivulets is in communication with the fluid in the sheaths of the pial arteries. (Key and Retzius.)

The terminal distribution of the arterioles of the pia in the cerebral substance is important in that each arteriole is surrounded by a wide lymph sheath which conveys the cerebro-spinal fluid from the cortical subarachnoid space into the substance of the brain and around the nerve cells. The arterioles are divided into long or medullary and short or cortical vessels. The short arterioles break up into a fine network in the grey matter of the cortex.

The cerebro-spinal fluid is a secretion from the cells lining the subarachnoid space and covering the choroid plexuses, and of course, like all secretions, comes from the blood; hence the main source of this fluid would appear to be from the choroid plexuses and from the arterioles of the pia mater. The choroid plexuses are covered by the same epithelium which lines the ventricles, and these cells and others lining the boundaries of the subarachnoid space seem to have a selective action which prevents the escape of antisyphilitic remedies, such as mercury and arsenic, from the blood into the cerebro-spinal fluid.

It is hardly to be believed that the cerebro-spinal fluid in health is not in movement. A stagnant fluid could not be the means of nourishment of brain cells, and movement is a law of life. Clinical experience in cases of intradural injury, meningitis, and hydrocephalus helps us to picture to some extent the course of the stream of the cerebro-spinal fluid. As the secretion of this fluid may be supposed to be most active in the region of the choroid plexuses of the ventricles, it must have means of exit from the ventricles. It can escape from the ventricles through certain known pathways—the foramen of Majendie, the foramina in the lateral recesses of the fourth ventricle (Luschka), perhaps also at the clefts described by Merkel in the descending cornua of the lateral ventricles, and perhaps also through some lymphatic vessels around arterioles on the surfaces of the ventricles into the cerebral substance. What is certain is that when the foramina in the roof of the fourth ventricle are closed by meningitis internal hydrocephalus results, so that the other means of escape of cerebro-spinal fluid from the ventricles can be only of slight service and are ineffective in emergencies. I have often noticed at post-mortem examinations that the foramen of Majendie is a distinct opening of considerable size. It is well shown in the "Atlas of Human Anatomy" of Spalteholz, Vol. III., Fig. 703. Testut and Poirier and Charpy give its measurements as 8 mm. × 6 mm.

In cases of intradural injury and hæmorrhage the fluid withdrawn by lumbar puncture a few hours afterwards is blood-stained. In the ordinary subarachnoid cerebral meningitis the fluid withdrawn by lumbar puncture is turbid and purulent. These results would not be obtained if the cerebro-spinal fluid was stagnant.

In cases of meningitis, especially of the fulminating variety, in which the pus is always subarachnoid in position, the spread of the inflammation from the basal cisterns upwards over the cortex towards the superior longitudinal sinus and Pacchionian bodies is explained in part, I think, by the current of cerebro-spinal fluid following this course. In this form of meningitis the arachnoid protects the subdural space, which is often unaffected by the presence of the pus beneath the arachnoid. The pus fills up the sulci between the convolutions and soaks into the cortex along the sheaths of the pial vessels. This is exactly the voyage which it is desired that remedies should take when mingled with the cerebro-spinal fluid in order that they may counteract the lethal effects of the poisoning of the cortical brain cells.

When pus collects in the cerebral subdural space it spreads out over the arachnoid as a flat sheet. This I have several times observed. The sheet of pus can be wiped off the outer side of the arachnoid—the membrane itself looking afterwards unaffected and the subarachnoid spaces between the convolutions being free of contamination. In cases of subdural hæmorrhage, which is an ingravescent condition and slowly extends from repeated small hæmorrhages, I have several times peeled the blood cyst thus formed off the outer surface of the arachnoid and then observed that neither the arachnoid membrane nor subarachnoid space beneath it was stained by blood pigment. These facts dispose of the view that there is any gross communication in man between the subdural and subarachnoid spaces.

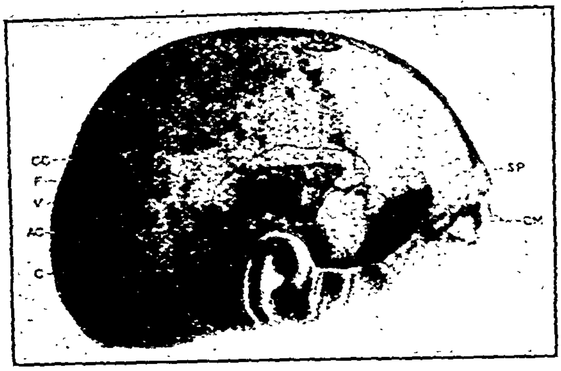
It would appear, then, probable that the cerebro-spinal fluid, having flowed out of the ventricles, passes down the spinal canal, and escapes along the sheaths of the spinal nerves. It also enters the numerous cisterns at the base of the brain, passes out through the sheaths of the cranial nerves, and streams upwards over the external face of the hemispheres under the cortical arachnoid. The largest cortical river flows from the "lac Sylvien" and divides into two streams, the "flumen Rolandien" and the "flumen Sylvien" (Testut). It is just in the territory watered by these streams that the manifestations of meningitis are often most advanced and most obvious. The larger streams divide into numerous rivulets which are found in all the sulci between the convolutions. The rivulets in the sulci are continuous, as we have seen, with the fluid in the sheaths around the pial arterioles. The arterioles penetrate the cortex and the cerebro-spinal fluid in their sheaths is conveyed to and flows around the cells of the grey matter of the cortex.

It is clear then that salvarsanised serum or other remedies introduced into the subarachnoid space of the brain will reach the nerve cells. What is the best plan to adopt in order to get the serum into the subarachnoid space of the brain? Should it be injected into the substance of the brain, or into the cisternæ at the base, or underneath the arachnoid of the cortex, or into the ventricles? There are certain obvious objections to the injection being made into the substance of the brain, and a considerable operation would be necessary if the serum was injected into the basal cisternæ. To inject the serum underneath the arachnoid over the cortex might injure the surface of the brain, and the opening made for the passage of the cannula might allow of its subsequent escape. These considerations seemed to point to the lateral ventricle as the best site for the injection.

II.—*The Method Chosen and Operation Performed*

The patient was anæsthetised and the head arranged in a position as nearly vertical as possible. A trephine opening was made to the right of the middle line just in front of the bregma. (Fig. 2.) The dura was then opened and the inner surface of the right cerebral hemisphere was gently drawn outwards by means of a retractor (1 cm. wide) bent at a right angle. It had previously been ascertained that the anterior cornu of the lateral ventricle was distant $6\frac{1}{2}$ to 7 cm. (roughly $2\frac{1}{2}$ to $2\frac{3}{4}$ inches) from the surface of the scalp at the mid-line on the vertex. A cannula (having a lumen of 1 mm. and a length of 3 inches) was then passed through the anterior part of the corpus callosum about a quarter of an inch to the right of the middle line. It was felt to enter a cavity—namely, the anterior cornu of the lateral ventricle. (Fig. 3.) The cannula was fitted with a stylet whose rounded end projected beyond the end of the cannula. (Fig. 4, A.) The passage of the stylet

FIG. 2.



Lateral view of skull with the position of the ventricles indicated. The site of the trephine opening for the introduction of the trocar and cannula used for perforating the anterior part of the corpus callosum is shown. The trocar and cannula (1 mm. lumen) perforate the corpus callosum about ¼ inch from the middle line, and enter the anterior cornu of the lateral ventricle. SP, Septum pellucidum. and cannula through the corpus callosum could not divide any vessel and might be thought of as pushing aside rather than cutting any of the commissural fibres of the corpus. On the entrance of the cannula into the lateral ventricle the stylet was withdrawn and cerebro-spinal fluid escaped, not continuously, for there was a distinct ebb and flow due to the arterial pulsations or to the respiratory movements. A rubber tube attached to a graduated glass vessel was then fixed to the cannula and the infusion into the ventricle commenced, at first with normal saline solution and then with salvarsanised serum; of the serum varying quantities have been used from 35 c.c. to 60 c.c. As the infusion proceeded it was noticed that the brain bulged into the trephine opening, but on closer inspection it was clear that the bulge was not a brain hernia, but that the cortical subarachnoid space was filling up with fluid. The 90 c.c. of fluid (salt solution and serum) took about 20 minutes to infuse and the pressure varied from 6 inches to 18 inches. No ill-effects have occurred from the injection of the serum into the ventricle. In the first case the fluid flowing very slowly the glass vessel was raised when a little respiratory difficulty occurred which was probably due to pressure in the fourth ventricle, the fluid not escaping quickly enough through the foramen of Majendie.

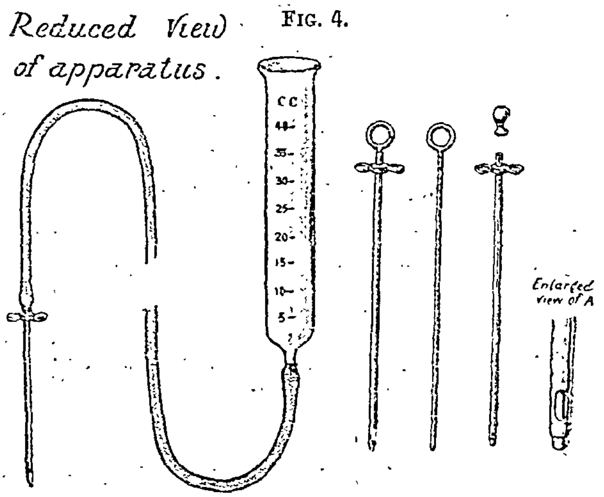
FIG. 4.



It only remained at the conclusion of the infusion to withdraw the cannula from the lateral ventricle and to stitch up the scalp, which in each case has healed by first intention. No ill-effects have followed the infusion. I have now introduced salvarsanised serum on five occasions into the lateral ventricle; twice in two patients and once in a third patient. The first operation was done on Feb. 25th, 1914, and was repeated on this patient on March 11th, 1914. This case appears to be improved, but Dr. Campbell will no doubt record the results at a later stage. Only a very large experience would justify a claim that the new methods would cure or arrest cerebral or spinal disease, as typified in general paralysis or tabes. In the third case, as related above, an unsuccessful attempt was made to infuse the serum by way of the subdural space, and a fortnight later the serum was introduced into the lateral ventricle. To the serum in this third case was added 0·009 gramme of neosalvarsan: that is one-hundredth of the intravenous dose. The serum used in these cases was obtained from blood drawn one hour after the intravenous injection of neosalvarsan.

On the operation being performed a second time in one of the cases it was noticed that there was a considerable collection of fluid within the dura, the brain being somewhat shrunk away from the dura. This fluid was allowed to run out by lowering the head, and a space then existed beneath the dura which would have taken all the salvarsanised serum that was available, but it was decided to infuse the serum again into the ventricle. The collection of fluid beneath the dura was cerebro-spinal fluid which had escaped from the subarachnoid cistern around the corpus callosum. Between the inferior border of the falx and the corpus callosum there is a large cistern—the spatium subarachnoidale corporis callosi. The wall of this space is broken by the passage of a spatula which is passed down between the inner surface of the brain and the falx cerebri to the corpus callosum, and cerebro-spinal fluid at once flows out of the cistern.

The method above described may perhaps be useful for introducing remedial agents into the cerebral cerebro-spinal fluid in other diseases of the brain besides that caused by syphilis. Sleeping sickness, meningitis, tetanus, and epilepsy are such diseases. The passage of the cannula through the corpus callosum appears to be innocuous, and the operation as a whole with reasonable care is free of all danger.

Addendum.

When this paper had been completed (April 20th, 1914) Dr. Purves Stewart kindly drew my attention to one by Dr. Marinesco and Dr. Minea published a month before. Marinesco and Minea[1] state that Marinesco in 1911 began to treat syphilis of the nervous system by injecting into the spinal arachnoid cavity the serum of syphilitic subjects who had been treated with salvarsan, and that in some cases good results were obtained in spinal syphilis and in the gastric crises of tabes. In their history of the subject they refer to the following:—1. Robertson[2] adopted the same treatment, and claimed amelioration in 50 per cent. of his cases. 2. Swift and Ellis in the Rockefeller Institute adopted the following technique. An hour after an intravenous injection of salvarsan they drew 40 c.c. of blood; this was centrifuged after coagulation. The next day to 12 c.c. of the serum were added 18 c.c. of physiological saline solution and the mixture was heated for half an hour to 56° F. A certain quantity of this diluted serum was injected into the spinal arachnoid of tabetics and general paralytics. 3. Several observers have tried injection of salvarsan into the spinal arachnoid. 4. Sicard and Lapointe, after preliminary experiments with physiological saline solution, injected 1/10th of a milligramme of mercuric cyanide dissolved in 5 c.c. of saline solution into the cerebral subarachnoid space, and later tried minimal doses of neosalvarsan by the same method. 5. Förster in general paralytics injected partly into the cerebral arachnoid and partly into the ventricles 20 c.c. of their own serum.[3] Marinesco and Minea make bilateral subarachnoid injections of serum salvarsanised *in vitro*, in the neighbourhood of the second frontal convolution. "We think," they say, "that the best apparatus is that of Neisser-Polak, by which the puncture can be made in less than a minute, and which makes a minimal opening; we believe that a trephine opening is needless even if it is desired to introduce a considerable quantity of fluid. For the present, at all events, we prefer serum salvarsanised *in vitro* by adding 40 or 50 milligrammes of neosalvarsan to 5 c.c. of serum obtained from the patient and rendered inactive. That is the dosis optima tolerated by the brain and one which very rapidly arrests the movements of the treponema pallidum. ...... The injections should be limited to the subarachnoid space and should not damage the cerebral cortex."

[3] Congrès de Psychiatrie et de Neurologie, November, 1912.

It will be seen that Marinesco and Minea refer to Förster as having injected serum into the ventricles of general paralytics, but in the *Münchener Medicinische Wochenschrift*[4] a different reading of Förster's paper is given as follows: "Förster read a paper at the Congress at Jena (Nov. 1st and 2nd, 1913) on Some Inoculation Experiments. He obtained by cranial puncture fragments of the brains of general paralytics, and planted them in guinea-pigs and monkeys. These fragments of the cerebral cortex contained active spirochætes in large numbers. He concluded by saying that '*we might take advantage* of the well-known susceptibility of the spirochæte to the antibodies in the blood by bringing these bodies into direct contact with the brain by injecting the patient's own serum into the subdural space or the ventricle.'" Unfortunately, I have not yet been able to obtain a copy of the transactions of the Jena Congress. The plan of cranial or orbital puncture for the introduction of remedies into the cranial cavity does in no way commend itself to me. The remedy in these desperate cases should be given in a scientific and precise manner. The "minimal opening" seems to me utterly wrong. It is impossible with a "minimal opening" of the cranial cavity or by passing a hollow needle through the sphenoidal fissure[5] to know exactly where the remedy has been injected. A trephine opening and a deliberate operative method is the only way at present known of scientifically injecting remedies into the cranial cavity. The circle of bone if thought desirable can be replaced at the conclusion of the operation. Desperate diseases require desperate remedies if any good is to be attained. Some may think apparently that a trephine opening is a desperate measure, but no one with any experience of modern cranial surgery would give his assent to such a view.

Post-Graduate College, West London Hospital.—A conversazione was held at the West London Hospital on Wednesday evening, May 27th. The guests were received by the senior surgeon (Mr. A. Baldwin) and the dean of the college (Mr. Donald J. Armour). An admirable musical performance was given by the string band of King Edward's Horse, and kinematographic views of the Panama Canal and of various interesting continental localities were shown. Some really excellent drawing-room magic was provided by Mr. Herbert J. Collings. There were exhibitions of optical, surgical, ophthalmic, X ray, and other scientific instruments, drugs, and medical publications. Dr. R. R. Elworthy showed favus and other preparations, and Dr. Reginald Morton stereoscopic and other radiographs. Refreshments were provided in the lecture-room.

THE TREATMENT OF PARENCHYMATOUS SYPHILIS BY INTRACRANIAL MEDICATION.

By HARRY CAMPBELL, M.D. Lond., F.R.C.P. Lond.,
PHYSICIAN TO THE WEST END HOSPITAL FOR DISEASES
THE NERVOUS SYSTEM, ETC.

Syphilitic diseases of the central nervous system fall under two heads—those in which the spirochætes infest the meninges and the walls of the blood-vessels, producing such lesions as gummata, meningitis, and endarteritis; and those in which the parasites get lodged between the nerve cells (i.e., in the perineuronic lymph spaces), giving rise to a primary parenchymatous degeneration, of which dementia paralytica, tabes dorsalis, and tabo-paresis are the commonest manifestations.

These two varieties of syphilis of the nervous system—the *interstitial* and the *parenchymatous*, as we may term them—exhibit many differences. The most noteworthy of these is that which relates to the effect of treatment upon them. While the interstitial variety is in large measure amenable to antisyphilitic remedies (salvarsan, mercury, potassium iodide) conveyed through the blood, parenchymatous syphilis, on the other hand, is wholly, or all but wholly, uninfluenced by treatment of this kind. The explanation probably lies in the fact that the drugs in question are incapable of percolating the walls of the capillaries which supply the lymph environing the nerve cells of the central nervous system, and thus are unable to reach the spirochætes ensconced between these cells.

The problem which confronts us in the treatment of parenchymatous syphilis would thus seem to be, how to get our spirillicidal remedies conveyed to the perineuronic lymph spaces. A ready means presents itself. All that is necessary is to introduce them into the subarachnoid space, either directly, or indirectly *viâ* the cerebral ventricles. Dr. F. W. Mott has long taught that the perineuronic lymph and the cerebro-spinal fluid are practically the same; and Dr. F. L. Golla has recently shown that a certain amount of the cerebro-spinal fluid in the subarachnoid space does, in point of fact, flow by way of the perivascular lymph spaces of the brain and spinal cord into the perineuronic lymph spaces, whence it drains off into the capillary venules. The method he adopts is to inject the subarachnoid cavity with colloidal carbon, allowing the animal to survive the injection some days, so as to give time for the translation of the carbon particles. These do not pass through animal membranes, and thus can only travel along open channels. Dr. Golla has kindly afforded me the opportunity of examining microscopically sections of the brain and spinal cord of animals thus treated, and it has been quite easy to trace the dark particles along the perivascular sheaths into the perineuronic lymph spaces, and even indeed into the nerve cells themselves. We thus see that, though spirillicidal substances cannot be conveyed to the perineuronic spaces through the blood stream, they can be made to reach these spaces by the route described, thus coming to grips with the spirochætes.

A question of importance in connexion with this mode of treatment is the direction in which the cerebro-spinal fluid flows within the subarachnoid space. Does the direction of the flow, e.g., permit of our remedies, when introduced into the spinal sac, reaching the cerebral cortex?

The cerebro-spinal fluid appears to be secreted partly by the cells covering the choroid plexuses within the ventricles, and partly by those lining the subarachnoid space. That derived from the ventricles escapes into the subarachnoid space by certain apertures, notably by the foramen of Majendie in the roof of the fourth ventricle—i.e., it passes chiefly, if not entirely, into the lower, subtentorial cranial chamber. As regards the flow of the cerebro-spinal fluid contained in the subarachnoid space, it is probably sluggish, moving mainly caudal-wards, though influenced somewhat by gravity. The flow is probably in large measure determined by the rhythmic pulsations (cardiac and respiratory) of the brain and spinal cord. These by commoting the fluid lead to an ebb and flow at the foramen magnum, the incisura tentorii (connecting the upper and lower cranial chambers), and the various orifices between the ventricles and the subarachnoid space. Hence some interdrainage of the fluid is continually taking place between the spinal sac and the lower cerebral chamber (containing the cerebellum, medulla, and pons), between the lower and the upper cerebral chambers, and again between the ventricles and the cranial subarachnoid space. In short, these rhythmic commotions lead to such a churning up of the fluid that a substance introduced into any part of the subarachnoid space (supra-tentorial, infra-tentorial, or spinal) tends to diffuse itself throughout the entire space. Thus when colloidal carbon is introduced subdurally above the tentorium it blackens the entire brain and spinal cord, and even to some extent the interior of the ventricles. The like happens when it is injected into the spinal arachnodural sac, though in this case little blackening of the cerebral hemispheres occurs. Indeed, Goldmann, after injecting trypan blue into the spinal sac, found them unstained. Golla, on the other hand, employing colloidal carbon and allowing some days to elapse before destroying the animal, found definite blackening of the hemispheres.

It would appear from these injection experiments that a considerable interchange of the fluid takes place between the spinal sac and the lower cranial chamber (at the foramen magnum), but that as regards the upper and the lower cranial chambers (communicating with one another at the incisura tentorii) the flow is mainly caudal-wards; and that while it is possible to convey our medicaments more or less evenly throughout the entire cerebro-spinal axis by introducing them into the upper cranial subarachnoid space, and also to reach the entire spinal cord, bulb, and cerebellum, by introducing them through the spinal sac, it is not possible by this latter method to convey more than a very small fraction of them to the cerebral hemispheres. This explains why in tabes intraspinal injections usually suffice, and why in general paralysis they are comparatively useless. If we rely upon intraspinal injections in the latter disease, the flow of the cerebro-spinal fluid from the spinal sac into the cranial cavity should be encouraged by raising the foot of the bed and allowing the patient's head to be at a lower level than the sacrum; also by urging him to turn about from side to side, and thus by commotion of the fluid to favour the diffusion of its spirillicidal contents. But even so we shall not succeed in carrying more than a very small proportion of the injections to the main seat of the spirochætes—the cerebral cortex. (It must not be forgotten, in considering the beneficial results of intraspinal injections in dementia paralytica, that the lesions in this disease are not confined to the cerebrum, but that they also affect the cerebellum, bulb, and spinal cord.)

It was the consciousness of our inability to convey our remedies in sufficient quantity to the cerebral cortex by the intraspinal route that led me to approach Mr. C. A. Ballance with regard to the possibility of introducing them directly into the cranial cavity. I had seen such striking results from the employment of intraspinal injections of salvarsanised serum in tabes as to make me hopeful of equally good results in dementia paralytica, if only the serum could be conveyed in sufficient quantity to the cerebral cortex. I had hoped that it could be introduced directly into the subarachnoid space of the upper cranial cavity by means of a small trephine opening, but Mr. Ballance has convinced me, by actual demonstration on the operating table, that it is very difficult, if not impossible, to introduce more than a very small quantity of fluid in this way. For this method to be successful we shall have to dispense with bulky remedies and rely upon remedies which are effective in quantities not exceeding a few cubic centimetres.

Mr. Ballance decided that the best way to introduce so large a quantity as, say, 40 c.c. of serum into the cranial subarachnoid space would be viâ the anterior horn of the lateral ventricle, by means of a cannula passed along the side of the falx cerebri through the corpus callosum; and this operation he performed successfully on a case of general paralysis on Feb. 25th. The patient made a rapid recovery. The operation was repeated on March 11th, and this time five drops of Fowler's solution were added to the serum. Convalescence on this second occasion was attended by slight mental disturbance, the result, I am inclined to think, of the Fowler's solution. There is no doubt that this patient's mental state has improved since these operations, but how far the improvement is the result of the treatment it is yet too early to say. Mr. Ballance has twice successfully performed the same operation on a second case of general paralysis. In this case the cortical degeneration had already reached an advanced stage, and I am not satisfied that any substantial improvement in the mental condition has been effected.

The intraventricular operation was undertaken in the belief that by its means a considerable proportion of the serum introduced is enabled to reach the upper cranial chamber, where it can circulate freely over the cerebral cortex. We have seen, however, that most, if not all, of the intraventricular cerebro-spinal fluid escapes through the openings of the fourth ventricle into the subarachnoid space of the inferior cranial chamber, and that thereafter it tends to pass downwards through the foramen magnum, rather than upwards through the incisura tentorii. This suggests that the trend of the serum injected intraventricularly is in the same direction. For this reason it is advisable to keep the head low after the intraventricular operation so as to favour the passage of the fluid through the incisura; but even assuming that only a small proportion of the serum injected intraventricularly reaches the cerebral cortex, we may, I think, safely conclude that much more reaches it by this method than by the intraspinal one, owing to the much greater supply of serum which reaches the inferior cranial chamber by the intraventricular method. The most satisfactory way of ascertaining to what extent the intraventricular cerebro-spinal fluid reaches the cerebral cortex would be by injecting the ventricles with colloidal carbon, an experiment which Dr. Golla has not been able to carry out with the animals at his disposal.

I have said that in tabes spinal injections usually suffice, for by their means the whole of the affected area of the central nervous system can be reached by the injections. There is, however, one form of tabes in which the question of resorting to intracranial injections presents itself—that form, namely, in which optic atrophy, generally of a rapidly progressive character, occurs. There is every reason to believe that the atrophy in these cases is due to the presence of spirochætes in the immediate neighbourhood of the optic nerves. It should be observed that the arachnoid membrane forms but a loose investment round the optic nerves, and thus allows the cerebro-spinal fluid to circulate freely about them. Dr. Golla's experiments have shown that when colloidal carbon is introduced subdurally into the upper cranial chamber the walls of the peri-optic subarachnoid space are blackened with carbon particles, and, moreover, that these can actually be traced into the nerves themselves. Now, it is true that the optic nerves can be reached by intraspinal injections, but certainly not so effectively as by the intracranial route. It was for this reason that I sought the help of Mr. Ballance in a case of tabetic optic atrophy with complete blindness of one eye and almost complete blindness of the other. This was the case in which the attempt was made to introduce the serum subdurally, and in which it was found impossible to get more than a very small quantity to remain under the membranes. Directly the cannula was removed, almost the whole of what had been introduced escaped through the opening in the dura. In a subsequent operation the intraventricular method was adopted, and there can, I think, be little doubt that this method affords the most effective way of reaching the optic nerves, for the serum rapidly passes into the peri-optic subarachnoid spaces, where it can soak into the optic nerves. The patient recovered from the operations, but the optic neurons had already been injured beyond recovery, and he has since lost the small degree of sight that was left to him at the time of the second operation. Nevertheless, it seems reasonable to hope that we may be able to arrest these cases of optic atrophy by means of suitable intracranial injections.

A word of caution in conclusion. The plan of treating syphilitic diseases of the central nervous system by the introduction of remedies into the cerebro-spinal fluid opens a new chapter in therapeutics, and has, I believe, a great future before it; but it is one beset with many dangers, and needs to be carried out with the utmost caution, not only in regard to strict asepsis—that goes without saying—but also as regards the remedies employed, and the strength, number, and intervals of the injections. It must not be forgotten that in introducing remedies into the cerebro-spinal fluid we are, as it were, going behind one of nature's defences—the capillaries of the central nervous system. When, e.g., arsenic is administered intravenously, intramuscularly, or by the mouth, it does not reach the neurons of the central nervous system; it is prevented from reaching them by the local capillaries, which constitute an important line of defence against poison circulating in the blood. When, therefore, it is introduced into the cerebro-spinal fluid only very minute doses shall be employed.

Wimpole-street, W.

THE INTRATHECAL INJECTION OF SALVARSANISED SERUM.

BY GORDON W. SPENCER, B.A., M.B., B.C. CANTAB.,
HOUSE PHYSICIAN, BRISTOL ROYAL INFIRMARY.

THE diseases of tabes dorsalis and general paralysis of the insane were, until quite recently, always looked upon as being "parasyphilitic" in origin, or, in other words, diseases which follow on in the wake of syphilis rather than being definitely attributable to it. Following the discovery of the spirochæta pallida by Schaudinn and the successful inoculation of anthropoid apes by Metchnikoff, Neisser, and others, the researches of Mott,[1] Noguchi,[2] Marie,[3] and Levaditi, who have found the spirochæta pallida in films from the brains of general paralytics, have conclusively proved the syphilitic origin of the diseases in question.

These diseases were usually treated with mercury and potassium iodide; very little benefit was derived from this or other antisyphilitic treatment, but the reason for the disease not responding to treatment was not at first obvious. An explanation has been found in the selective action of the choroid plexus, which allows practically no drugs or antibodies to pass through into the cerebro-spinal fluid. In proof of this are the facts: (*a*) that the spinal cord and fluid do not become stained in jaundice; (*b*) that mercury and arsenic are not present, or only in minute traces after the patient has been taking the drug for some time; and (*c*) that if trypan blue be injected intravenously the cord or fluid does not become stained. It is, therefore, obvious that if we are to reach the spirochætes, which we now know are present in the brain and cord, we must place our antisyphilitic remedies into the cerebro-spinal fluid itself.

Intravenous injections of salvarsan and neosalvarsan having failed to give relief it occurred to Dr. Swift[4] of the Rockefeller Institute, to try the intrathecal injection of the serum of a patient who had had salvarsan. Nierenstein,[5] working with atoxyl, has shown that arsenic by itself has no effect upon trypanosomes *in vitro*. Upon adding protein death occurred after a certain time, but this time was much lessened if the atoxyl was allowed to combine with the protein first and then added to the trypanosomes. This then provides the rationale of our present treatment, as there is only a minute quantity of protein in the cerebro-spinal fluid; so the neosalvarsan is given intravenously first, and then the serum derived from the patient, which will therefore contain the arsenic-protein compound, is injected intrathecally.

Technique.—An intravenous injection of neosalvarsan 0·75 grm. is first given. In this series of experiments the neosalvarsan has been given in concentrated solution, never more than 10 c.c. of doubly distilled water being used to dissolve it, and the injection has been made with a "record" syringe without previously dissecting out the vein. The two main points to notice are: (1) the importance of using doubly distilled water, which almost reduces to nothing the reaction to the drug; and (2) that the injection should be made by puncture with a hypodermic needle without dissection, as patients are beginning to grumble and to refuse treatment on account of the tell-tale scar left in the anticubital fossa.

Twenty-four hours after the injection of neosalvarsan blood is withdrawn from a vein, again by puncture with a needle. Scrupulous asepsis must be observed, and it is advisable to wear sterilised rubber gloves during the operation. The blood is allowed to flow into six centrifuge tubes, each of about 15 c.c. capacity, and these are then plugged with sterile wool. After standing for an hour, to allow the blood to clot, the clot is loosened round the edges by means of a sterile platinum needle, and the tubes are then centrifugalised. The resulting serum is collected from the lot into a sterile tube.

Lumbar puncture is now performed in the ordinary way, and about an equivalent quantity of cerebro-spinal fluid to the amount of serum to be injected is drawn off. A syringe is then filled with the serum, and the serum forced into the intrathecal space. About one ounce of serum was given in each case. It is hardly necessary to emphasise the fact that all the above operations must be carried out with the strictest aseptic precautions, as the slight resistance of the spinal cord and cerebro-spinal fluid to infection is well known, and the danger to the life of the patient, should such occur, is obvious.

I have found the above method by far the most satisfactory, though it differs in many ways from that used by other observers. Campbell[6] withdraws the blood after six hours. A few experiments were performed to find out when the greatest percentage of arsenic is in the blood. The method used was colorimetric, and, contrary to expectation, it was found that the second day revealed the greatest quantity. Further experiments are necessary, and are being carried on, before this can be definitely asserted, but there was sufficient evidence to justify the delay to 24 hours in withdrawing the blood after the injection of neosalvarsan. This delay also ensures that the combination between the arsenic and the proteins in the blood has taken place.

By centrifugalisation a larger quantity of serum is obtained from a smaller quantity of blood, and I do not think that the risk of infection is increased if proper care is taken. Further, only 1½ to 2 hours need elapse between withdrawing the blood and the intrathecal injection. In this respect my method again differs from that of Dr. Campbell, who allows the blood to stand for 12 hours in a sterile bottle.

If trypan blue be injected by lumbar puncture it has been found that only the cord and brain stem become coloured with the pigment. It is therefore possible that none of the salvarsanised serum reaches the brain. If this is so, this method is only applicable in the treatment of tabes dorsalis and other syphilitic lesions of the cord, and cannot be used for the relief of general paralytics. In the cases about to be described an examination was made for the presence of arsenic in the blood, urine, and cerebro-spinal fluid 24 hours after the injection of neosalvarsan. Speaking roughly, arsenic was found in the blood and urine, but not in the cerebro-spinal fluid.

With regard to the reaction to the intrathecal injection it was found that in those cases where the injection was being given for the relief of the lightning pains of tabes the pains became very severe, almost excruciating, a few hours after the injection, but that they gradually passed off and the patient was altogether free from them at the end of 36 to 48 hours. There was usually a slight rise in temperature and pulse-rate during the first day, but this fell during the second. No untoward instances or complications occurred throughout the series.

Seven Cases of Tabes Dorsalis.

CASE 1.—Female, aged 38. No definite history of infection. Symptoms: Lightning pains which occurred daily; ataxy. Signs: Absent knee-jerks, Argyll Robertson pupils, and glove and stocking anæsthesia. Wassermann reaction positive. Has had no lightning pains for past four months; reflexes unaltered; health improved.

CASE 2.—Male, aged 34. Had gleet 28 years ago; no chancre. Seven years' history of increasing difficulty in walking. Had lightning pains about every other day. Signs: Absent knee-jerks, Argyll Robertson pupils, rombergism, patches of anæsthesia, and ataxy. Wassermann reaction positive. Has had no pains since injection; rombergism less marked; walks more steadily and can now feel the ground as he walks.

CASE 3.—Male, aged 39. Had soft sore 15 years ago. Had lightning pains for 11 years, with increasing difficulty in walking. The pains were very bad and he took morphia to relieve them. Signs: Bedridden, absent knee-jerks, glove and stocking anæsthesia, incoördination, and incontinence. Wassermann reaction positive. The pains were absent for a week after injection but came on again. No lasting improvement noticed. The patient's blood from which the serum was made gave none of the reactions for arsenic, showing that possibly he was unable to split up the neosalvarsan molecule. Arsenic was recovered from the urine.

CASE 4.—Male, aged 42. Had gonorrhœa but no chancre. Four months' history of lightning pains, which had been very severe. Wassermann reaction positive. Has had no return of the pains since injection.

CASE 5.—Male, aged 46. Had gonorrhœa. Seven years' history of increasing difficulty in walking. Severe lightning pains, often requiring morphia. Signs: Absent knee-jerks, incontinence of urine, Argyll Robertson pupils, and glove and stocking and girdle anæsthesia. Wassermann reaction positive. Has had no lightning pains since injection. Gait improved and patient's health much better; rombergism less marked. Only slight improvement in incontinence.

CASE 6.—Male, aged 54. Ten years' history of lightning pains and difficulty in walking. Signs: Absent knee-jerks, Argyll Robertson pupils, and rombergism. Has had no pain since injection; walk steadier; feels better.

CASE 7.—Male, aged 52. Had a chancre 23 years ago. Three years' history of lightning pains. Charcot's knee one year. Signs: Argyll Robertson pupils and absent knee-jerks. Wassermann reaction positive. Pains much less since injection; health better; walk steadier.

Five Cases of Sclerosis and Interstitial Cord Lesions.

CASE 1.—Male, aged 29. Nine months' history of stiffness of legs and difficulty in walking. Signs: Lateral nystagmus; knee-jerks brisk, patellar clonus present on left side, and double extensor plantar response; incontinence of urine and fæces; greatly impaired mental state. Wassermann reaction positive. After injection slight improvement occurred in the movement of the legs and in his general mental condition. He seemed to know that he was passing his motions, but would not trouble to control them. The improvement was only temporary.

CASE 2.—Female, aged 38. Spastic paralysis of both legs for 18 months with contractures. Ankle clonus present on right side; extensor plantar response. Wassermann reaction positive. Intrathecal injection made no definite improvement.

CASE 3.—Male, aged 31. Sensory and motor aphasia; right hemiplegia; incontinence. Wassermann reaction positive after injection of neosalvarsan. After intrathecal injection patient appeared to take notice of his surroundings, which he had not done before, and he was able to move his right leg slightly. No improvement in incontinence, and he did not recover his speech.

CASE 4.—Male, aged 44. Pain at the bottom of his back and in his legs for eight months. Knee-jerks brisk, double extensor plantar response, rombergism; anæsthesia over feet; pupils equal and active; gait ataxic. Wassermann reaction positive. Much improved by injection; tingling in feet disappeared, rombergism less, ataxy improved and has had no pain; no alteration in reflexes.

CASE 5.—Male, aged 39. Soft sore four years ago. Difficulty in walking, vomiting and lassitude for one year. Knee-jerks exaggerated, double extensor plantar response, patellar clonus present; no alteration in sensation; pupils active; rombergism present. Wassermann reaction positive. The pain and vomiting were relieved and the rombergism was less marked, but patient does not feel any better.

McIntosh[7] has subdivided syphilitic lesions of the brain and spinal cord into "interstitial" and "parenchymatous." In the former the meninges, blood-vessels, and neuroglia are primarily affected, with secondary involvement of the neurons through compression and softening; in the latter the neurons themselves are affected. Tabes and general paralysis belong to the parenchymatous variety, and the above results seem to show that this type of cord lesion is more affected by the intrathecal injection than the interstitial.

Campbell[6] has published a series of 10 cases which seem to bear this out, but the patients treated by him were also given mercury. The above cases received nothing but the salvarsan, and so the improvement made is entirely due to the intrathecal injection, and this may account for the poor results obtained with the interstitial cases, as considerable improvement can be effected in them by the ordinary antisyphilitic treatment.

Conclusions.—The intrathecal injection of salvarsanised serum offers a hopeful method of treating and arresting the progress of tabes and other parenchymatous diseases of the spinal cord. Before its introduction these cases resisted all our efforts, and finally drifted into the asylums and workhouses. A cure of the lightning pains can almost definitely be promised. The injections, if carried out with special aseptic care and technique, do not endanger the patient's life. There is a great future before this treatment when further work has been done in perfecting it, as we are now working on definite scientific lines for the cure of a condition which has previously baffled all our efforts, mainly because the pathology has not been fully understood.

In conclusion, I wish to express my very best thanks to Professor F. H. Edgeworth for his kindness in allowing me to publish these cases and for his invaluable help and sympathy with the work. The technique of the method of neosalvarsan injection was due to Dr. J. A. Nixon, whom I wish to thank for this and for the permission to publish one of the above cases. The Wassermann reactions were carried out by Professor I. Walker Hall by Wassermann's original method, and this fact is sufficient guarantee of their absolute accuracy. I am also greatly indebted to Mr. J. Taylor for much valuable work in the estimation of the arsenic in the blood and urine.

THE OCCURRENCE OF ASCITES OF A NON-TUBERCULOUS ORIGIN IN CHRONIC RECURRENT DIARRHŒA IN CHILDHOOD.

BY F. J. POYNTON, M.D. LOND., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO OUT-PATIENTS, UNIVERSITY COLLEGE HOSPITAL, AND HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;
AND
HUGH PATERSON, M.D. EDIN.,
MEDICAL REGISTRAR AND PATHOLOGIST, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

FROM time to time cases of intractable recurrent diarrhœa are met with in childhood, which though not tuberculous in nature may nevertheless develop ascites. In a recent paper Poynton, Armstrong, and Nabarro,[1] in the second case they record and again in the fifth, note such an occurrence, but in neither instance was the event fatal. The combination of obstinate diarrhœa with profound wasting and ascites in early childhood is one so intimately associated with abdominal tuberculosis that this fatal case, giving *proof* of its existence in a non-tuberculous condition, appears to us worth recording, not only because we think it is a fact not very generally recognised, but because it is a small addition to the literature of a condition of very great difficulty and much importance.

In general terms this class of case shows the following characters. Following not infrequently an acute infantile gastro-enteritis, the case develops an obstinate recurrent diarrhœa, varied sometimes by intervals of meteorism and constipation. There is in bad cases profound infantilism, and there may be general anasarca, tetany, cœliac symptoms, and even arthritic changes. The dieting of such children is a matter of extreme difficulty, but a considerable number after the fifth year seem to make an almost spontaneous though slow recovery. The case we record here is clearly one of this class, as the description will show.

The patient, a male aged 3½ years, the second child of healthy parents with no tuberculous history in the family, was admitted for "wasting" into the Hospital for Sick Children, Great Ormond-street, on Dec. 19th, 1913. He had been a healthy boy with a good digestion until he was a year old, when he had an attack of "infantile cholera." Since that time he had never been well, but had gradually drifted into the state of marasmus for which he was admitted to the hospital. The illness had shown the usual features. Any attempts at pressing forward the diet resulted in breakdown with vomiting and diarrhœa. His weight on admission was 21½ lb., and though there were records of a gain of 1½ lb. in a week the usual history had been that of a stationary weight or a slight loss. There was a greedy desire for water, and when the attacks came on vomiting and the passage of large, white, undigested, offensive stools. When the motions improved the child would make a change for the better, but only to fall back again as quickly at the next relapse. At times there was considerable abdominal pain. All kinds of devices had been tried in dietary, but none had suited. His appearance was very characteristic in its waxy pallor, but apart from the marasmus he did not

appear acutely ill and the temperature was never above normal. Previously to admission there had been a general anasarca which had, however, mostly disappeared. There was nothing abnormal discovered in the heart or lungs. The abdomen was rather distended. The liver was not felt and no masses were detected. There was no discoverable ascites, and the urine was not abnormal. The first week after admission the weight rose a pound, and then followed an attack of diarrhœa. The motions were clay-coloured and unformed, but later became greenish and contained mucus.

Dr. D. N. Nabarro reported upon the motions as follows: "Reaction acid.—Smears showed a preponderance of Gram-positive bacilli. Smell 'butyric,' not fæcal. Culture showed only typical bacillus coli. Agglutination tests were made with typhoid, paratyphoid B and four strains of dysentery bacilli (1–25, 1–50, 1–100). The results were all negative except a partial reaction (1–25) with one strain of dysentery."

After the attack of diarrhœa the weight fell to 19 lb., and then there was once more some improvement, but in the middle of January vomiting commenced and the motions now became dark. On the 16th anasarca began to show again, and fluid was detected in the abdomen. In spite of every care the child died from heart failure on the 25th, the weight having risen to 23 lb. At no time was there a rise of temperature.

The essential features of the necropsy were: (1) A general infiltration of the tissues with œdema fluid; (2) the entire absence of any evidence of tuberculosis; (3) the presence of a pint of straw-coloured fluid in the abdomen and about 5 oz. in each pleural cavity; (4) general œdema of the walls of the gastro-intestinal tract, the mucous membrane of which was thinned in some places, but was for the great part œdematous and thickened and showed no ulceration; (5) definite enlargement of the mesenteric glands, which were translucent on section, but showed no signs of tuberculous change; (6) extreme fatty change in the liver; and (7) no apparent change in the pancreas.

The brain and spinal cord were not examined and the other organs showed no obvious changes. Bacteriological investigation after death failed to discover the dysentery bacillus. Microscopical examination of the various organs showed, on the whole, remarkably few points of interest. The liver showed definite fatty changes of high degree and particularly obvious at the periphery of the lobules. The pancreas showed small circumscribed areas of leucocytic infiltration between the acini, but there was no fibrous change. The gastro-intestinal tract showed œdema of the walls, and there were circumscribed areas of leucocytic infiltration in the submucosa and mucosa of the stomach and colon. In the colon there was also much destruction of the glandular epithelium, and in the ileum the submucosa was in places much thinner than normal. The mesenteric glands appeared normal. The cardiac muscle showed no obvious changes. The renal epithelium appeared normal. The Malpighian corpuscles of the spleen were poorly marked.

Poynton, Armstrong, and Nabarro in their paper describe a fatal case of this kind, but differing in the absence of ascites. From that case Nabarro isolated after death the bacillus of dysentery, but on this occasion failed to do so. There were, however, some decided points of resemblance in the results of the necropsy in these two cases, notably the absence of ulceration in the intestinal tract and the presence of extreme fatty change in the liver. Further, foci of infiltration with leucocytes in the gastro-intestinal tract were described in both, and above all it was apparent that the condition was not one of gastritis, enteritis, or colitis, but a widespread affection of the digestive apparatus apparently in its nature infective.

From whatever point of view these cases are studied they present features of intense interest. The etiology is obscure, and we have still to learn whether it is a clinical group only or a group dependent upon some special infection. The treatment is extraordinarily difficult and demands the most trying of all tests both for doctor and parents the patience, one might almost term obstinacy, to struggle on month after month with almost a starvation diet. No fact is more certain in the present state of our knowledge than that any attempt to hasten progress is to court disaster. The more experience one has of these cases the more is any phenomenal gain in weight rather a warning of impending disaster than a sign of any real progress. The relation of the cœliac symptoms to the actual disease is yet another point of interest, and, lastly, three is the question of the diagnosis.

It is abdominal tuberculosis that provides the great difficulty. These cases waste; they have abdominal pain, recurrent diarrhœa and constipation, distension, and sometimes fever. They may pass mucus or even a little blood, and they may have ascites; nevertheless, the necropsy shows an entire absence of any tuberculous process in the body.

As the writers in the paper already alluded to pointed out, these cases in their recurrent attacks may reach a degree of illness from which, if they were tuberculous in nature, it would seem impossible to recover, and certainly to recover on more than one occasion. There is no evidence of tubercle elsewhere in the body and the various tuberculous reactions have been negative. Examination of the fæces will show the absence of tubercle bacilli. The temperature is not so constantly raised and may be subnormal. There are no masses of tuberculous deposit in the abdomen, and our experience has been that the ascites when it occurs is part of a general anasarca, which in its sudden onset is a remarkable feature of these cases. Again, the previous history of an infantile "cholera" is suggestively frequent, and the difficulty in the dieting appears to us greater than in most cases of abdominal tuberculosis. The occurrence of tetany and laryngismus and of rheumatic pains in the limbs are suggestive of the nature of these cases, as also is the infantilism, with a peculiar pallor and remarkable softness of the general musculature.

The practical physician will, however, in analysing these distinctions, recognise that they are relative rather than absolute indications, and if further proof were needed it might be stated that there are probably few who have had experience of such cases and have not for months, perhaps for years, thought some of them were probably tuberculous in nature and have been led to change their diagnosis by an unexpected, slow, but complete recovery.

It is a curious fact that the periods of constipation with great meteorism may lead to the suspicion that we are dealing with an entirely different condition—namely, Hirschsprung's disease; but this may be the case, and it is quite possible that, as Poynton, Armstrong, and Nabarro record, a condition almost indistinguishable may result.

The occurrence of this ascites is an interesting example of a clinical difficulty in which the combination of physical signs in two widely different processes creates a striking likeness in the results that are produced. The ascites in abdominal tuberculosis is clearly the result of the local irritation of the peritoneum by numberless foci of miliary tubercle; the ascites in these cases of chronic diarrhœa is a transudate which occurs also in all loose tissues, and in very severe cases in probably all the soft tissues of the body. It is an ascites comparable to that in renal disease, and it is possible, we suppose, that some change in the renal tissues may actually occur, although it is not obvious to ordinary methods of examination. This œdema of the loose tissues is a very suggestive occurrence, and when, as is usually the case, it precedes the ascites is strong evidence that the latter is not tuberculous in origin. In this particular case we think it greatly assisted the diagnosis of the non-tuberculous nature of the illness.

In conclusion, we would repeat that the essential point in this contribution is the actual *proof* of a definite ascites in this condition.

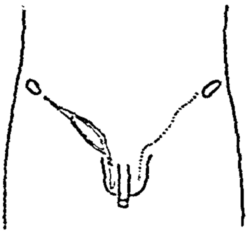
AN OPERATION FOR UNDESCENDED TESTICLE.

BY RALPH THOMPSON, CH.M. VICT., F.R.C.S. ENG.,
SURGEON IN CHARGE OF THE GENITO-URINARY DEPARTMENT, GUY'S HOSPITAL; SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN.

WHEN an operation designed to bring down an undescended testicle is undertaken two main difficulties present themselves. One is the lengthening or the partial removal of the structures which connect the testicle to the body. I do not propose to deal with this difficulty in the present paper. The second difficulty is the retention of the testicle in the scrotum. It is with this difficulty that this paper is concerned.

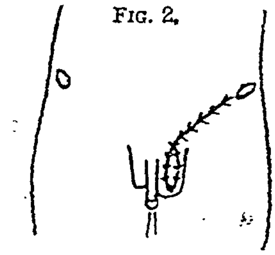
I have, in two cases of undescended testicle which have occurred at Guy's and the Victoria Hospitals, adopted the following plan for retaining the testicle in the scrotum. The usual incision is made for the exposure of the external opening of the inguinal canal, with two exceptions—it is longer and it is curved. The incision commences just internal to the anterior superior spine, and proceeds in a sinuous manner into the scrotum. It may be divided, for the purposes of description, into three parts of equal length. The first part lies half an inch above, and parallel with, the outer half of Poupart's ligament. (Fig. 1, left side.) The second part is curved with its convexity directed downwards and outwards. It begins just above the middle of Poupart's ligament and terminates near the pubic spine. The third part curves downwards into the scrotum, and is of equal length to each of the two other parts of the incision. Its convexity is directed upwards and inwards. The external ring is exposed and any hernia treated in the usual way. The vas is isolated with its accompanying artery and vein. The cremasteric plexus of blood-vessels and lymphatics is removed between ligatures. A finger is introduced into the cavity of the scrotum and the testicle is brought down and placed in the scrotum, where it is retained by an assistant. The extremities of the middle part of the incision are then united by a curved incision, whose convexity is directed upwards and inwards (Fig. 1, right side); and an oval flap of skin and subcutaneous tissues, extending down to the external oblique muscle, is dissected and isolated. This oval flap is then transferred to the scrotal part of the incision and sutured to both sides of this part, so that its lower apex lies in the lowest part of the scrotal portion of the incision. The rest of the wound is then sewn up in the usual way. When the suturing is complete the wound is as shown in Fig. 2.

FIG. 1.



Left side, incision indicated by dotted line. Right side shows formation of oval flap.

FIG. 2.



To show incision, sutured edges, and position of inguinal flap when sewn up.

By this means the scrotum is appreciably enlarged and, as it were, stiffened by a portion of tissue which contains no "dartos" muscle, and therefore remains uncontracted. The simplicity of the operation and its successful results in two cases have tempted me to place it on record.

Wimpole-street, W.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.—Auricular Flutter in Acute Rheumatic Carditis.

A MEETING of this section was held on April 24th, Dr. LEONARD G. GUTHRIE, the President, being in the chair.

Dr. H. MORLEY FLETCHER showed a case of Amyotonia Congenita.

Mr. A. E. MORTIMER WOOLF exhibited a case of Arthritis of the Left Shoulder in a boy aged 8. Three years before he had been under treatment for fibroid lung of tuberculous origin. The present trouble started with pain in the joint followed by limitation of movement and muscular wasting. An X ray examination showed caries of the head of the humerus.

The PRESIDENT showed a case of Pneumonia followed by Encephalitis.

Mr. PHILIP TURNER showed: 1. A case of Cubitus Varus after fracture of the lower end of the humerus which was treated by osteotomy of the humerus above the condyles. The operation was successful in removing the deformity, and there was also a great improvement in the function of the arm. 2. A case of Syphilitic Cirrhosis of the Liver with Ascites, which had been treated by a Talma-Morison operation. Though the operation was followed by a considerable collection of fluid in the peritoneal cavity calling for tapping, this had not re-collected and the abdomen was now considerably smaller. The general condition had also improved.

Dr. E. A. COCKAYNE exhibited a case of Mongolian Blue Spots. The patient was aged 11 months and the parents were both Jews. The spots when first seen at the age of 9 weeks were of a clear slaty-blue colour unaltered by pressure.

Dr. R. A. CHISOLM showed a case of Enlargement of the

Spleen which was considered to be an example of splenic anæmia of infancy. It was proposed to treat it by salvarsan, and if this was not followed by improvement splenectomy would be considered.

Mr. A. H. **TODD** showed a case of Complete Double Hare-lip without any Cleft of the Palate. Congenital bilateral mucous fossæ were also present in the lower lip.

Dr. H. D. **ROLLESTON** and Dr. J. N. **MACBEAN ROSS** exhibited a case of Lymphatic Leukæmia which had been successfully treated with benzol.

Dr. G. A. **SUTHERLAND** read a paper on Auricular Flutter in Acute Rheumatic Carditis. He pointed out that while the importance of the endocardial, pericardial, and myocardial changes in rheumatic infection was generally recognised, there was another factor to be considered in some cases—viz., the development of an abnormal rhythm of the heart. The onset of an abnormal rhythm did not necessarily mean that the heart was irregular in its action, as tested by the ordinary methods. As a matter of fact, one of the striking features of acute carditis was the regularity of the action, however rapid the rate, as tested by the pulse or the apex beat. These beats were dependent on the action of the ventricles, and in the majority of cases an abnormal rhythm was developed in the auricles. He had recently met with two cases in which there was apparently an abnormal rhythm of the auricles, and which was recognised only on taking a venous tracing in the neck. Tracings were shown which seemed to point to a condition of auricular flutter. He thought that a heart already weakened by disease might find itself hopelessly crippled by the supervention of some such rhythm, and the signs of cardiac failure might be rapidly induced or gravely aggravated. While an exact diagnosis of auricular flutter could be made only by means of an electric cardiograph, he thought the polygraph gave very suggestive tracings. As practical points for further investigation he suggested that attention be paid to the following possible indications of this form of disordered rhythm: (1) Attacks of cardiac asthma (great dyspnœa) occurring suddenly and without accompanying variations in the cardiac condition; (2) a triple or galloping or cantering rhythm heard on auscultation; (3) pericarditis without effusion and with great respiratory distress; and (4) the presence of the pulsus alternans.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Election of Officers.—Exhibition of Specimens.—The Etiology of Eclampsia.

THE annual meeting of this section was held on May 7th, Dr. W. S. A. **GRIFFITH**, the President, being in the chair. The following officers and members of Council were elected for 1914–15: President: Dr. W. S. A. Griffith. Past-Presidents: Sir Francis H. Champneys, Bart., Sir J. Halliday Croom, Mr. Alban Doran, Dr. Amand Routh, Sir William J. Smyly, Mr. W. D. Spanton, and Dr. Herbert R. Spencer. Vice-Presidents: Dr. W. W. Chipman, Dr. T. Watts Eden, Dr. F. W. N. Haultain, Dr. M. Handfield-Jones, Dr. Arnold W. W. Lea, Dr. H. Macnaughton-Jones, Dr. G. H. Drummond Robinson, Dr. Heywood Smith, and Dr. Walter W. H. Tate. Honorary Secretaries: Dr. C. Hubert Roberts and Dr. Cuthbert Lockyer. Other members of Council: Dr. G. F. Blacker, Mr. J. S. Fairbairn, Dr. A. E. Giles, Mr. William Gilliatt, Mr. Bryden Glendining, Dr. T. B. Grimsdale, Dr. J. P. Hedley, Dr. J. B. Hellier, Dr. Eardley Holland, Dr. J. M. Munro Kerr, Dr. F. J. McCann, Dr. R. G. McKerron, Mr. J. D. Malcolm, Mr. G. F. Darwall Smith, Dr. Clifford White, Mr. H. Beckwith Whitehouse, Dr. J. Abernethy Willett, and Dr. Thomas Wilson. Representative on Library Committee: Dr. H. Russell Andrews. Representative on Editorial Committee: Dr. John Phillips.

Dr. **FLORENCE WILLEY** showed: 1. Endothelioma of Uterus removed from a single woman aged 45. For three years the patient had suffered with hæmorrhage, and for six months from recurring abdominal pain. Subtotal hysterectomy was performed, and on opening the enlarged uterus, which measured 4 by 4 inches, a fluctuating globular tumour was found bulging into the cavity, and on incision clear fluid escaped. The rest of the tumour appeared to be filled with soft lobular masses of the consistency of fat. The tumour measured 3 inches in diameter, and was only partially encapsuled; part of the growth invaded uterine muscle tissue. On section the tumour was an endothelioma. The specimen was referred to the Pathology Committee, who reported it as a "perithelioma." 2. Specimen illustrating Partial Development of a Placenta on the Decidua Capsularis and Implantation on a Submucous Fibromyoma.

Dr. C. E. **PURSLOW** (Birmingham) showed: 1. Uterus with Red Degeneration and Early Pregnancy removed from a married woman whose period was ten days overdue, during which time she suffered with violent abdominal pain. The tumour, which showed well-marked red degeneration, was on the anterior wall. The uterine cavity was filled with blood clot and contained an amniotic sac having a diameter of half an inch. 2. Uterus with Multiple Fibroids and Placenta Prævia, removed by hysterectomy.

Dr. J. P. **HEDLEY** showed a specimen of 19 pieces of Fœtal Bones which he had removed from the uterus of a woman, aged 37, three years after a miscarriage at about the fourth month. At the time of operation the finger in the uterus found a thick mass an inch in diameter which bristled with the spicules of bone now shown. Dr. Hedley believed the pregnancy to be intra-uterine and not interstitial.—Remarks were made on this specimen by the **PRESIDENT**, Dr. **PURSLOW**, Dr. G. F. **BLACKER**, and Dr. R. D. **MAXWELL**.

Dr. E. ***ATHOLE ROSS*** *(for Mr.* ***JOSEPH E. ADAMS****) showed* a specimen of Carcinoma of the Uterus in a child, aged 2½, who for three weeks before admission had a blood-stained discharge, and passed clots. Examination of the abdomen showed a tumour, partly cystic, in the hypogastrium between the bladder and the rectum. The urine contained no blood. Abdominal section was performed on June 18th, 1913, and a mass of soft growth the size of a golf ball was found in the recto-vesical space, obscuring the position of the uterus. It was incised, and a hæmorrhagic growth of a malignant nature discovered. It could not be removed. The child died two months after the operation. At the post-mortem examination a large mass of growth occupied the pelvic cavity, arising apparently from the uterus. Careful examination of the removed organs showed the ovaries and tubes intact, and that both body and cervix of the uterus were largely replaced by breaking-down growth which had extended into Douglas's pouch and grown into the cavity of the vagina and bladder. The growth appeared to be a "papilliferous or villous carcinoma arising in the glandular epithelium of the body of the uterus" (Dr. Ross). There was no evidence of tubercle.—Remarks were made by the **PRESIDENT**, and the specimen was referred to the Pathology Committee.

Dr. **HERBERT WILLIAMSON** showed a specimen of Intussusception through a Gastro-enterostomy Wound occurring during labour in a patient, aged 28, in the thirty-fourth week of her second pregnancy. In 1908 and 1909 she had symptoms of gastric ulcer and underwent two operations, one being a gastro-enterostomy at the Great Northern Hospital. She made a good recovery, and in 1912 was delivered of a healthy child after a normal pregnancy. Her second pregnancy commenced in July, 1913. There was vomiting, which became more severe on Dec. 24th, 1913. It ceased, but recurred on Jan. 25th, 1914, and she was admitted to St. Bartholomew's Hospital on Feb. 24th last. The urine contained a trace of albumin and a considerable quantity of acetone and diacetic acid. On Feb. 25th she expelled a stillborn child. Two hours later the stomach was greatly distended and a loud succussion splash was evident. The patient looked very ill. The stomach was washed out by a soft tube, and gas and a pint of dark blood-stained fluid drawn off. Acute dilatation of the stomach was suspected, but she became rapidly worse. The temperature was 101° F., and the pulse 140, with cyanosis and collapse. No surgical interference was thought advisable on account of the general condition. She died 36 hours later. On post-mortem examination the stomach contained gas, dark fluid, decomposing blood clot, and a large tract of intussuscepted intestine which appeared through the wound. The bowel mass was 15 inches in length and was gangrenous, and consisted of the upper portion of the jejunum.

Mr. **CLIFFORD WHITE** showed a specimen of Volvulus of the Cæcum occurring in connexion with labour. The patient was aged 25 years and expected her second child in May, 1914. Four years ago an appendix abscess was drained in the Hastings Hospital. The resulting scar was weak and prominent. At the seventh month of the present pregnancy she was very constipated, for which she took castor oil. On

Feb. 24th she consulted a medical man for abdominal pain. On March 1st a dead seven months child was born before the midwife could reach the house. Her general condition was at first good, but later, when the district resident medical officer of Queen Charlotte's Hospital visited her, the pulse was 140. Enemata failed to get the bowels to act. When Dr. Clifford White saw her the abdomen was distended and tense, and there was a large hernia of the appendectomy scar which could not be reduced. In the right lumbar region an indefinite mass could also be felt. The patient was removed to the Samaritan Free Hospital for Women, and the abdomen opened in the line of the old scar. The sac contained offensive fluid and the cæcum, which was gangrenous. There was a volvulus of the cæcum and about 3 inches of the ascending colon. The cæcum, a few inches of colon, and 10 inches of the ileum were removed, and Paul's tubes tied in. Death occurred on March 6th. No necropsy could be obtained. The interest of the case was as to when the volvulus occurred and the difficulty in diagnosing the cause of collapse occurring in a patient soon after labour.

Dr. **JAMES YOUNG** (Edinburgh) read a paper on the Etiology of Eclampsia and the Albuminuria of Pregnancy, and discussed their relation to accidental hæmorrhage. Placental disease was especially apt to be found in these toxæmias. That this relationship was not a necessary one, however, was usually supposed to be shown by the fact that in acute cases the placenta often looked healthy. But he showed that whilst this was so, if some days had elapsed between the acute attack and the birth of the placenta there was always a massive recent necrosis. This discovery indicated that there was a necessary relationship, and that it was with the earliest, often unrecognisable, stages of the placental death that a toxæmia was associated. Dr. Young referred to the fact that it was not difficult to show that the chorionic elements depended directly and immediately upon the maternal blood for their nourishment, and so long as this was not implicated, could live where there was no fœtal circulation. The causes of such placental disease were merely an exaggeration of changes normally present in lesser degree. It could be proved that the implication of the circulation, which ended in placental death, was not due to a toxæmic state. It could, moreover, be proved that the cause of accidental hæmorrhage was something apart from a toxæmia, for 50 per cent. of such cases were unassociated with any sign of poisoning. The inevitable conclusion from these researches was that the placental disease was the cause of the toxæmia. If the placenta was completely detached or was delivered early there would be no chance for the development of a toxæmia. Dr. Young supplied experimental proof of the conclusion that it was the early autolytic products of a dying patch of placenta that caused the toxæmia. By autolysing healthy placenta for short periods he had isolated a material that, when injected subcutaneously into lower animals, reproduced the three cardinal features of eclampsia—(1) severe convulsions, (2) focal necrosis in the liver, especially in the peripheral zone of the lobules, and (3) degenerative changes in the kidney, especially in the region of the convoluted tubules. The convulsions, it was interesting to note, came on within 30 seconds. He had controlled his experiments by the injection of extracts of other organs which gave negative results.—The paper was discussed by the PRESIDENT, Dr. WILLIAMSON, Dr. MACMASTER, Dr. H. OLIPHANT NICHOLSON, and Dr. EDEN.—Dr. YOUNG replied.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Early Nervous and Mental Cases.

THE quarterly meeting of this association was held at the Medical Society's rooms, London, on May 19th, under the presidency of Dr. JAMES CHAMBERS.

Dr. WOLSELEY LEWIS proposed—

That [illegible] as Part [illegible] of the London County Council (General Powers) Bill [illegible] the visiting asylums committee of its special [illegible] as a Statutory Committee under the Lunacy [illegible] with the [illegible] of Asylums [illegible] that [illegible] in the above mentioned Bill be made to [illegible]

This was carried.

The SECRETARY (Dr. M. Abdy Collins) read a letter from the Board of Control intimating that the Treasury had placed at the disposal of the Board £1500 for the year 1914–15 to encourage scientific research into the causes and treatment of mental disease and mental defect.

On the motion of Dr. J. G. SOUTAR, seconded by Dr. R. G. ROWS, the meeting passed a series of resolutions thanking the Board of Control for their efforts in the promotion of research connected with the specialty, and offering to nominate members of the association who would be available for consultation in furtherance of the manner of disposing of the grant to the best advantage, and suggesting that grants be given to (*a*) individual workers, and (*b*) universities and public bodies acting together or separately.

Dr. HELEN BOYLE, of the Lady Chichester Mental Hospital, read a paper entitled "Some Observations on Early Nervous and Mental Cases with Suggestions as to Possible Improvement in our Methods of Dealing with Them." It was a plea for unification of teaching treatment with regard to nervous and mental diseases. She said that early nervous and mental cases were inseparable logically in the abstract, and still less separable in practice. Dr. F. W. Mott had declared that locomotor ataxy was pathologically the same disease as general paralysis of the insane, and she suggested that the discovery of this fact would not have been postponed until now but for locomotor ataxy having been labelled nervous and general paralysis of the insane mental, and the cases of that disease packed off to an asylum. She spoke of her experience of 19 years, which was largely concerned with nervous and mental cases, as asylum officer, and later in connexion with the Lady Chichester Hospital for early mental and nervous cases among the poor. During that experience she had often known non-recovery in recoverable cases, and was much impressed by the lack of unity of conception or treatment. The differences and reasons fell under two heads: (1) those relating to the general treatment and opinions held on mental and neurotic cases as a whole; and (2) reasons connected with individual and special treatment of definite groups of patients. The cases were treated by the general practitioner, who in most instances had had no special training in neurology or insanity; or they might fall under the care of psychotherapeutists or physicians or surgeons or professors of various faiths, such as Christian Scientists. The last person to see an early mental case was usually the specialist in that class of disease, the alienist. Dr. Boyle deprecated the separation in teaching of neurology from psychiatry, and the absence of wards for early nervous and mental cases, and consequent lack of teaching regarding those cases for students and nurses in the great general hospitals which possessed medical schools. All specialists on the nervous system should be conversant with brain conditions as well as nervous. There were many cases of mental disease wrongly labelled nervous and sent to undergo Weir-Mitchell treatment, under which treatment the unoccupied mind, with nothing to distract it, fed upon itself. Moreover, the separation of neurology from psychiatry confused the public mind. She repeated a paradox she often used, that insanity began before the person was insane; defective mental health often existed long before the person became certifiable. Some acute cases cleared up under appropriate treatment, and were no more fit for an asylum than were the temporary insanities of typhoid fever or pneumonia. The cases which it was really important for students to see were not those of delirium tremens, but the early uncertifiable cases, the early obsessional and early melancholic, the hypochondriacal; these cases could never be taught by books. No practitioner could escape the early nervous and mental cases, and the welding of the two specialties would do away with much of the fear of detention on the part of patients suspecting a mental breakdown. She referred with gratitude in this connexion to the generosity of Dr. Maudsley in providing an institution for the treatment of London's poor mental patients.

Sir GEORGE H. SAVAGE thought there was a good deal of misapprehension in the minds of many people on the subject of the paper, for many declared that if only certain patients had been seen earlier they would never have been sent to an asylum. He emphasised the importance of a general knowledge of medicine in all who practised the specialty. He fully agreed that the psychologist and the neurologist should work together. There was a public prejudice against lunacy and against the medical men who specialised in it, and they had the notion that the one idea in the minds of the latter was to send people to asylums, forgetful of the numbers who were prevented from entering asylums owing to appropriate early treatment.

Dr. **PERCY SMITH** pointed out the administrative difficulty concerning the provision of beds for early mental cases in general hospitals. At St. Thomas's and other general hospitals there was an out-patient department for mental cases, and he believed it was of great benefit. But there were some cases which from the first required asylum treatment.

Dr. **JAMES STEWART** expressed the hope that the public would be brought to see the difficulties which were associated with this subject, and supported the authoress's plea for a closer association between the neurologist and the alienist.

Dr. **BEDFORD PIERCE** hesitated to speak on this subject because we knew so little as to the causes of these early cases of mental disorder and so little as to what was best to be done for them. He recently, for the purposes of a debate, inquired the views of a number of physicians and busy practitioners, and the inquiry revealed a remarkable difference of opinion.

Dr. **NOEL SERGEANT** deprecated importing too much sentiment into the matter and the talk of the "shame" of certification, especially as certification was a safeguard both for the general public and for the patient himself, and so giving him the best chance for recovery.

Dr. **T. B. HYSLOP** said that in border-line cases there had always been a difficulty, and probably there always would be. And there was the risk of illegality in institutions which were not under the regulations of the Lunacy Act. He also discouraged any tendency of one specialty, such as psychiatry, throwing stones at another, neurology.

Dr. **H. F. HAYES NEWINGTON** said that a large section of the public thought that insanity was cured by scientific observations and the use of sera, but the prime and most important step towards cure was to take the patient out of the surroundings in which the defect occurred, and, indeed, there seemed reason to believe that this one step was responsible for some patients getting well. There were many difficulties in connexion with placing patients under suitable care, and these the bulk of the public had no conception of.

Dr. **H. CORNER**, speaking of an experience of 17 years, during part of which time he had had care of a home, said he fully recognised the difficulties of the position. But there was need for early treatment of cases on lines which the existing law did not provide for. He detailed suggestions which he made to the authorities in connexion with two attempts at legislative amendment.

Dr. **C. F. FOTHERGILL** spoke of the importance of taking harassed and run-down people away from their mischievous surroundings as the first step towards cure, and thought they should be, at least in the first instance, sent to hospital instead of to an asylum. Moreover, the fear of certification was calculated to drive a threatening case over the borderline into actual insanity. This was especially the case of the poor, who could not afford residence in some of the special homes set apart for this work.

Mr. **C. T. STREET** considered that certification was the crux of the whole matter, but thought there was much nonsense talked about certification. It was difficult to give many cases proper treatment without certification.

Dr. **LEWIS** said there seemed to be a strong opinion in favour of some alteration of the law with regard to certification of patients and it was true that some patients sent to asylums would have been better treated outside those institutions. For this purpose, however, there should be a system of notification as opposed to certification, though perhaps there would be a difficulty in that from the point of view of the public. The medical students' curriculum was already so crowded that he did not think it wise to attempt to include definite teaching of insanity in it, especially as that subject could not be learnt from books.

Dr. **WILLIAM R. DAWSON** agreed with what had been said as to the exaggerated ideas which prevailed concerning effects of certification upon patients. His experience was that it had no adverse effect upon them. The relatives were much more upset by certification than were the patients themselves. He referred also to the unsuitability of ordinary hospital nurses for mental cases. With regard to the unification of the specialties of neurology and psychiatry it was much easier for the psychiatrist to become a neurologist than *vice versâ*, for psychiatry could not be learnt from books; there was only one road to knowledge of mental diseases and that was active residence in an asylum and being constantly with mental cases.

Dr. **MAURICE CRAIG** commented on the regrettable lack of hospital accommodation for acute mental cases in the poorer classes, the need for which was manifested by the great number of applications for admission to the Lady Chichester Hospital which Dr. Boyle was in charge of. On this question of certification a great deal was made of the "liberty of the subject," but the lawyers were really greater opponents of that in this matter than the alienists.

Dr. **J. FRANCIS DIXON** agreed with Dr. Craig's remarks, and thought some provision should be made for asylums taking in voluntary boarders.

Mr. **H. E. HAYNES** thought the present English law bore hardly upon mental patients.

The **PRESIDENT** thought that if so-called early mental cases could be treated in general hospitals far-reaching benefits would accrue, and perhaps clinical teachers themselves would adopt a different line if that were done.

Dr. **BOYLE** replied, pointing out that the class of case she was dealing with in the paper was not the certifiable ones at all, for they were already excellently treated. Her plea was on behalf of the early mental and nervous case which, from lack of proper provision, often became incurable.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held in the Royal Infirmary on May 20th, Dr. **JOHN PLAYFAIR**, the President, being in the chair.

Dr. **DAWSON TURNER** showed a female patient, aged 37, who had been cured of a recurrent carcinoma over the left sterno-clavicular joint. Her right breast had been removed for a scirrhus tumour in August, 1912. Recurrence took place in the following October. On admission on Feb. 3rd, 1914, there was a large tumour which measured 3 inches by 2½ inches and projected forwards 2½ inches from the sternum. She suffered considerable pain. Treatment consisted in the internal and external application of radium and the total dose amounted to 5510 mg. hours, with the result that pain was relieved and the growth gradually disappeared.

Mr. **JOHN FRASER** exhibited a boy, aged 5 years, who had developed tuberculous disease of the left middle ear and mastoid, with secondary involvement of the facial nerve and resulting facial paralysis. Operative treatment of the ear condition failed to relieve the paralysis, and at the end of a year there was no sign of recovery. The cervical glands became tuberculous, and 18 months ago they were removed. During the dissection the peripheral facial nerve was anastomosed to the central spinal accessory; a portion of the external jugular vein was excised and used to encircle the line of suture. Now at the end of 18 months muscular power was returning to the face.

Professor **ALEXIS THOMSON** showed: 1. A man, aged 32, who had suffered from extradural suppuration which followed an injury to his head. Pott's puffy tumour was present with signs of pressure on the motor area causing hemiplegia on the opposite side. The bone was extensively removed and autogenous staphylococcus vaccine administered, with the result that the man had recovered. 2. A boy, aged 11 years, after Resection of the Humerus for Sarcoma. The patient had been shown to the society in 1910, after an operation in September, 1909, in which the middle portion of the humerus was resected for a spindle-celled sarcoma of the periosteum. The disease had returned and the lower half of the humerus was removed in July, 1910, and again a portion of his fibula was inserted in its place. The disease had not returned and the humerus had grown in length.

Dr. **ROBERT A. FLEMING** showed: 1. A male, aged 18 years, suffering from a remarkably Dilated and Hypertrophied Heart with most marked præcordial pulsation. The present illness was believed to have started when he was 7 years old, but there was no definite history of rheumatic fever. The pulse was 116 and of typical water-hammer character. He had aortic stenosis with thrill and incompetence, and also mitral stenosis and incompetence. 2. A female, aged 22 years, suffering from Glycosuria and presenting some remarkable features. The sugar in the urine had varied from about 400 to 80 grains in the day. She was in good health but became very tired after slight exertion. Dr. W. Cramer contributed the following note: "The urine gave the typical glucosazone crystals, fermented, rotated polarised light to the right, and gave a positive Nylander reaction, but when tested with Fehling's solution gave a scarlet-red solution which darkened rapidly and turned black, depositing a black precipitate. This abnormal reduction was due to production of a colloidal solution of cuprous oxide (red) which was further reduced to colloidal copper (black). The reaction was due to the presence of glucose in a relatively concentrated urine which contained a high percentage of creatine and creatinine. If the urine was diluted with water, the ordinary typical Fehling reaction was obtained. The occurrence of the reaction indicated a glycosuria which was not associated with a polyuria."

Mr. DAVID WALLACE showed: 1. A case of Carcinoma of the Hepatic Flexure. The patient, a man aged 55, was seized with sudden pain in the right iliac fossa in April, 1913. Previously he had suffered much from constipation, associated with much pain in the bowels after taking purgative medicine. These symptoms had continued for 12 months. A mass was felt in the right lumbar region, but there was no visible peristalsis. The operation was done on May 14th, 1913, and a carcinoma of the hepatic flexure with secondary nodules in the liver was found. The ileum was laterally joined to the transverse colon. The patient made a good recovery, but was at present losing health. Mr. Wallace doubted whether there was any real advantage in short-circuiting in such cases, and stated that even an exploratory incision often hastened death. 2. Case of Renopelvic Calculus from a male aged 28 years. The usual pain in the right lumbar region with blood in the urine was present. X rays showed the presence of stone in the pelvis of the kidney. On Feb. 3rd, 1914, the calculus was removed through the pelvis; the incision in the pelvis was closed and the line of incision strengthened with fascia. No escape of urine occurred. The calculus was similar to three others in having large angular crystals on the surface. 3. A Renal Calculus in the substance of the kidney in a woman. The symptoms were anomalous, but the X rays gave a definite shadow and the percussion sign was present.

Mr. D. P. D. WILKIE showed a man in whom he had resected the posterior nerve roots for relief of the gastric crises of tabes. The symptoms commenced four years ago and nine injections of salvarsan were given, but without any benefit. The pains were so severe that the patient was laid low for two days every week with severe pain and vomiting. The other manifestations of tabes were relatively slight. Four weeks ago the operation was performed, the spines and laminæ of the third to the eighth dorsal vertebræ were removed, and the seven posterior nerve roots (fifth to eleventh) on each side were resected. Since the operation he had had no pain or vomiting (except one slight attack four days previously). There was no sensation in the skin and tissues of the back. There had been delay in closing of the wound by reason of the removal of the stitches too soon, it having been forgotten that the trophic influence had also been destroyed by the operation. Mr. Wilkie thought that several cases operated on in this way had not shown improvement on account of too few nerve roots having been removed.

Dr. D. CHALMERS WATSON exhibited a young man, aged 2[illegible] years, suffering from Chronic Indigestion. The affection had commenced a year ago with abdominal pain, nausea, flatulence, constipation, loss of weight (nearly 1 st.), and general lack of vigour, associated with marked ileal stasis and secondary gastric and colon stasis, the primary factor being, in all probability, due to adhesions in the ileo-cæcal region. There were three areas of definite tenderness on pressure: (1) in the right iliac region; (2) to the left of the umbilicus; and (3) over the right rectus muscle. The stomach was atonic and displaced downwards.

Dr. W. T. RITCHIE and Mr. J. M. GRAHAM showed a case of Pernicious Anæmia in a woman aged 5[illegible] years, which had been treated by the direct transfusion of blood. The patient had had two previous relapses after treatment by arsenic. The red cells amounted to 771,000 and hæmoglobin to 35 per cent. The anæmia increased in spite of arsenic. Transfusion was carried out on March 5th, 1914, the radial artery of her daughter being connected to the cephalic vein of the patient. Thereafter numerous nucleated red cells appeared, and her condition steadily improved. On May 15th the red cells numbered $2\frac{1}{4}$ million and the hæmoglobin 65 per cent. The chief effect of the transfusion seemed to be a stimulation of the bone marrow.

Mr. J. W. DOWDEN demonstrated: 1. A man who showed power of locomotion in spite of the absence of the head and neck of the femur (Charcot's disease of the hip without nervous symptoms). 2. A woman, aged 50 years, showing the benefit of a bone graft from the crest of the tibia implanted for ununited fracture of the neck of the femur with absorption.

Professor F. M. CAIRD showed: 1. A man, aged 31, who had been pitched from a bicycle against a wall; he had persisted in cycling seven miles after the accident and had the wound in the head dressed by a medical man. Two days later he went into hospital, when, on operating, a depressed fracture was found, the bone was elevated and the fragments of bone re-implanted. The patient made a good recovery. 2. A miner, aged 21 years, who, as a result of a fall of coal on his head sustained a wound and depression in the skull. The next day he was sent into hospital after the wound had been dressed by a medical practitioner. The wound furnished a growth of staphylococci. The depressed bone was elevated and the wound cleansed with 1:20 carbolic acid. The patient had made a good recovery, though there was a pulsating area on the skull over which he had to wear a shield.

Dr. CHARLES MCNEIL exhibited three children suffering from Chronic Dyspepsia to show the beneficial results of giving an emulsion of liquid paraffin. They suffered from chronic diarrhœa with wasting, recurrent bilious attacks, nocturnal enuresis, and malnutrition.

Mr. CHARLES W. CATHCART showed a man who two and a half years ago sustained a fracture of the lumbar spine which had probably caused crushing of the cauda equina and produced complete paraplegia. He had recovered his walking power, although no operation had been performed.

Dr. FRANCIS D. BOYD showed: 1. A case of Bronchiectasis to illustrate oxygen replacement and artificial pneumothorax. 2. A case of Diabetes with Acidosis to illustrate the benefit which might follow "oatmeal cure."

Mr. LEWIS BEESLY showed a girl aged 2 years. She had had tuberculous dactylitis when 9 months old, with abscess formation, and complete recovery after removal of sequestra. Five months later a painless enlargement around the left ulna developed. Tuberculous osteomyelitis in the proximal half of the diaphysis was diagnosed. Subperiosteal resection was performed on July 14th, 1913; primary union took place, and there had been no further sign of tuberculosis.

Mr. A. A. SCOT SKIRVING showed a man, aged 31 years, after very extensive operation four months ago for Squamous Epithelioma of the Left Upper Jaw. Owing to implication of the skin of the cheek no flap could be made use of. Accordingly the parts involved (including the left eye and part of the nose) were removed *en masse*, with the result that a large open cavity was left. Though smaller than at first, the cavity was still very large. A plastic operation to restore the mouth had been done, and a further plastic operation to close the cavity was shortly to be carried out by means of a flap from the scalp or from the left upper arm. Much help had been obtained at the operation from the intratracheal method of giving the anæsthetic and from preliminary ligature of the external carotid.

EDINBURGH OBSTETRICAL SOCIETY.

Gift of a Presidential Chair.—Stillbirth Registration.

A MEETING of this society was held on May 13th, Sir J. HALLIDAY CROOM, the President, being in the chair.

The PRESIDENT intimated the gift of a Presidential Chair from Dr. H. M. Church: it is decorated with the crest and motto of the society—viz., the beautiful head of Lucina (or Juno), the goddess who presided over marriage and childbirth, with an olive branch and young olives on either side, intertwined with the motto "Floreat Lucina." The society was founded in 1840.—Dr. CHURCH was very cordially thanked for his gift and made a suitable reply.

was to send people to asylums, forgetful of the numbers who were prevented from entering asylums owing to appropriate early treatment.

Dr. PERCY SMITH pointed out the administrative difficulty concerning the provision of beds for early mental cases in general hospitals. At St. Thomas's and other general hospitals there was an out-patient department for mental cases, and he believed it was of great benefit. But there were some cases which from the first required asylum treatment.

Dr. JAMES STEWART expressed the hope that the public would be brought to see the difficulties which were associated with this subject, and supported the authoress's plea for a closer association between the neurologist and the alienist.

Dr. BEDFORD PIERCE hesitated to speak on this subject because we knew so little as to the causes of these early cases of mental disorder and so little as to what was best to be done for them. He recently, for the purposes of a debate, inquired the views of a number of physicians and busy practitioners, and the inquiry revealed a remarkable difference of opinion.

Dr. NOEL SERGEANT deprecated importing too much sentiment into the matter and the talk of the "shame" of certification, especially as certification was a safeguard both for the general public and for the patient himself, and so giving him the best chance for recovery.

Dr. T. B. HYSLOP said that in border-line cases there had always been a difficulty, and probably there always would be. And there was the risk of illegality in institutions which were not under the regulations of the Lunacy Act. He also discouraged any tendency of one specialty, such as psychiatry, throwing stones at another, neurology.

Dr. H. F. HAYES NEWINGTON said that a large section of the public thought that insanity was cured by scientific observations and the use of sera, but the prime and most important step towards cure was to take the patient out of the surroundings in which the defect occurred, and, indeed, there seemed reason to believe that this one step was responsible for some patients getting well. There were many difficulties in connexion with placing patients under suitable care, and these the bulk of the public had no conception of.

Dr. H. CORNER, speaking of an experience of 17 years, during part of which time he had had care of a home, said he fully recognised the difficulties of the position. But there was need for early treatment of cases on lines which the existing law did not provide for. He detailed suggestions which he made to the authorities in connexion with two attempts at legislative amendment.

Dr. C. F. FOTHERGILL spoke of the importance of taking harassed and run-down people away from their mischievous surroundings as the first step towards cure, and thought they should be, at least in the first instance, sent to hospital instead of to an asylum. Moreover, the fear of certification was calculated to drive a threatening case over the border-line into actual insanity. This was especially the case of the poor, who could not afford residence in some of the special homes set apart for this work.

Mr. C. T. STREET considered that certification was the crux of the whole matter, but thought there was much nonsense talked about certification. It was difficult to give many cases proper treatment without certification.

Dr. LEWIS said there seemed to be a strong opinion in favour of some alteration of the law with regard to certification of patients and it was true that some patients sent to asylums would have been better treated outside those institutions. For this purpose, however, there should be a system of notification as opposed to certification, though perhaps there would be a difficulty in that from the point of view of the public. The medical students' curriculum was already so crowded that he did not think it wise to attempt to include definite teaching of insanity in it, especially as that subject could not be learnt from books.

Dr. WILLIAM R. DAWSON agreed with what had been said as to the exaggerated ideas which prevailed concerning effects of certification upon patients. His experience was that it had no adverse effect upon them. The relatives were much more upset by certification than were the patients themselves. He referred also to the unsuitability of ordinary hospital nurses for mental cases. With regard to the unification of the specialties of neurology and psychiatry it was much easier for the psychiatrist to become a neurologist than *vice versâ*, for psychiatry could not be learnt from books; there was only one road to knowledge of mental diseases and that was active residence in an asylum and being constantly with mental cases.

Dr. MAURICE CRAIG commented on the regrettable lack of hospital accommodation for acute mental cases in the poorer classes, the need for which was manifested by the great number of applications for admission to the Lady Chichester Hospital which Dr. Boyle was in charge of. On this question of certification a great deal was made of the "liberty of the subject," but the lawyers were really greater opponents of that in this matter than the alienists.

Dr. J. FRANCIS DIXON agreed with Dr. Craig's remarks, and thought some provision should be made for asylums taking in voluntary boarders.

Mr. H. E. HAYNES thought the present English law bore hardly upon mental patients.

The PRESIDENT thought that if so-called early mental cases could be treated in general hospitals far-reaching benefits would accrue, and perhaps clinical teachers themselves would adopt a different line if that were done.

Dr. BOYLE replied, pointing out that the class of case she was dealing with in the paper was not the certifiable ones at all, for they were already excellently treated. Her plea was on behalf of the early mental and nervous case which, from lack of proper provision, often became incurable.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held in the Royal Infirmary on May 20th, Dr. JOHN PLAYFAIR, the President, being in the chair.

Dr. DAWSON TURNER showed a female patient, aged 37, who had been cured of a recurrent carcinoma over the left sterno-clavicular joint. Her right breast had been removed for a scirrhus tumour in August, 1912. Recurrence took place in the following October. On admission on Feb. 3rd, 1914, there was a large tumour which measured 3 inches by 2½ inches and projected forwards 2½ inches from the sternum. She suffered considerable pain. Treatment consisted in the internal and external application of radium and the total dose amounted to 5510 mg. hours, with the result that pain was relieved and the growth gradually disappeared.

Mr. JOHN FRASER exhibited a boy, aged 5 years, who had developed tuberculous disease of the left middle ear and mastoid, with secondary involvement of the facial nerve and resulting facial paralysis. Operative treatment of the ear condition failed to relieve the paralysis, and at the end of a year there was no sign of recovery. The cervical glands became tuberculous, and 18 months ago they were removed. During the dissection the peripheral facial nerve was anastomosed to the central spinal accessory; a portion of the external jugular vein was excised and used to encircle the line of suture. Now at the end of 18 months muscular power was returning to the face.

Professor ALEXIS THOMSON showed: 1. A man, aged 32, who had suffered from extradural suppuration which followed an injury to his head. Pott's puffy tumour was present with signs of pressure on the motor area causing hemiplegia on the opposite side. The bone was extensively removed and autogenous staphylococcus vaccine administered, with the result that the man had recovered. 2. A boy, aged 11 years, after Resection of the Humerus for Sarcoma. The patient had been shown to the society in 1910, after an operation in September, 1909, in which the middle portion of the humerus was resected for a spindle-celled sarcoma of the periosteum. The disease had returned and the lower half of the humerus was removed in July, 1910, and again a portion of his fibula was inserted in its place. The disease had not returned and the humerus had grown in length.

Dr. ROBERT A. FLEMING showed: 1. A male, aged 19 years, suffering from a remarkably Dilated and Hypertrophied Heart with most marked præcordial pulsation. The present illness was believed to have started when he was 7 years old, but there was no definite history of rheumatic fever. The pulse was 116 and of typical water-hammer character. He had aortic stenosis with thrill and incompetence, and also mitral stenosis and incompetence. 2. A female, aged 22 years, suffering from Glycosuria and presenting some remarkable features. The sugar in the urine had varied from about 400 to 80 grains in the day. She was in good health but became very tired after slight exertion. Dr. W. Cramer contributed the following note: "The urine gave the typical glucosazone crystals, fermented, rotated polarised light to the right, and gave a positive Nylander reaction, but when tested with Fehling's solution gave a scarlet-red solution which darkened rapidly and turned black, depositing a black precipitate. This abnormal reduction was due to production of a colloidal solution of cuprous oxide (red) which was further reduced to colloidal copper (black). The reaction was due to the presence of glucose in a relatively concentrated urine which contained a high percentage of creatine and creatinine. If the urine was diluted with water, the ordinary typical Fehling reaction was obtained. The occurrence of the reaction indicated a glycosuria which was not associated with a polyuria."

Mr. DAVID WALLACE showed: 1. A case of Carcinoma of the Hepatic Flexure. The patient, a man aged 55, was seized with sudden pain in the right iliac fossa in April, 1913. Previously he had suffered much from constipation, associated with much pain in the bowels after taking purgative medicine. These symptoms had continued for 12 months. A mass was felt in the right lumbar region, but there was no visible peristalsis. The operation was done on May 14th, 1913, and a carcinoma of the hepatic flexure with secondary nodules in the liver was found. The ileum was laterally joined to the transverse colon. The patient made a good recovery, but was at present losing health. Mr. Wallace doubted whether there was any real advantage in short-circuiting in such cases, and stated that even an exploratory incision often hastened death. 2. Case of Reno-pelvic Calculus from a male aged 28 years. The usual pain in the right lumbar region with blood in the urine was present. X rays showed the presence of stone in the pelvis of the kidney. On Feb. 3rd, 1914, the calculus was removed through the pelvis; the incision in the pelvis was closed and the line of incision strengthened with fascia. No escape of urine occurred. The calculus was similar to three others in having large acicular crystals on the surface. 3. A Renal Calculus in the substance of the kidney in a woman. The symptoms were anomalous, but the X rays gave a definite shadow and the percussion sign was present.

Mr. D. P. D. WILKIE showed a man in whom he had resected the posterior nerve roots for relief of the gastric crises of tabes. The symptoms commenced four years ago and nine injections of salvarsan were given, but without any benefit. The pains were so severe that the patient was laid low for two days every week with severe pain and vomiting. The other manifestations of tabes were relatively slight. Four weeks ago the operation was performed, the spines and laminæ of the third to the eighth dorsal vertebræ were removed, and the seven posterior nerve roots (fifth to eleventh) on each side were resected. Since the operation he had had no pain or vomiting (except one slight attack four days previously). There was no sensation in the skin and tissues of the back. There had been delay in closing of the wound by reason of the removal of the stitches too soon, it having been forgotten that the trophic influence had also been destroyed by the operation. Mr. Wilkie thought that several cases operated on in this way had not shown improvement on account of too few nerve roots having been removed.

Dr. D. CHALMERS WATSON exhibited a young man, aged 20 years, suffering from Chronic Indigestion. The affection had commenced a year ago with abdominal pain, nausea, flatulence, constipation, loss of weight (nearly 1 st.), and general lack of vigour, associated with marked ileal stasis and secondary gastric and colon stasis, the primary factor being, in all probability, due to adhesions in the ileo-cæcal region. There were three areas of definite tenderness on pressure: (1) in the right iliac region; (2) to the left of the umbilicus; and (3) over the right rectus muscle. The stomach was atonic and displaced downwards.

Dr. W. T. RITCHIE and Mr. J. M. GRAHAM showed a case of Pernicious Anæmia in a woman aged 51 years, which had been treated by the direct transfusion of blood. The patient had had two previous relapses after treatment by arsenic. The red cells amounted to 770,000 and hæmoglobin to 35 per cent. The anæmia increased in spite of arsenic. Transfusion was carried out on March 8th, 1914, the radial artery of her daughter being connected to the cephalic vein of the patient. Thereafter numerous nucleated red cells appeared, and her condition steadily improved. On May 13th the red cells numbered 2½ million and the hæmoglobin 65 per cent. The chief effect of the transfusion seemed to be a stimulation of the bone marrow.

Mr. J. W. DOWDEN demonstrated: 1. A man who showed power of locomotion in spite of the absence of the head and neck of the femur (Charcot's disease of the hip without nervous symptoms). 2. A woman, aged 50 years, showing the benefit of a bone graft from the crest of the tibia inplanted for ununited fracture of the neck of the femur with absorption.

Professor F. M. CAIRD showed: 1. A man, aged 31, who had been pitched from a bicycle against a wall; he had persisted in cycling seven miles after the accident and had the wound in the head dressed by a medical man. Two days later he went into hospital, when, on operating, a depressed fracture was found, the bone was elevated and the fragments of bone re-implanted. The patient made a good recovery. 2. A miner, aged 21 years, who, as a result of a fall of coal on his head sustained a wound and depression in the skull. The next day he was sent into hospital after the wound had been dressed by a medical practitioner. The wound furnished a growth of staphylococci. The depressed bone was elevated and the wound cleaned with 1:20 carbolic acid. The patient had made a good recovery, though there was a pulsating area on the skull over which he had to wear a shield.

Dr. CHARLES MCNEIL exhibited three children suffering from Chronic Dyspepsia to show the benefiical results of giving an emulsion of liquid paraffin. They suffered from chronic diarrhœa with wasting, recurrent bilious attacks, nocturnal enuresis, and malnutrition.

Mr. CHARLES W. CATHCART showed a man who two and a half years ago sustained a fracture of the lumbar spine which had probably caused crushing of the cauda equina and produced complete paraplegia. He had recovered his walking power, although no operation had been performed.

Dr. FRANCIS D. BOYD showed: 1. A case of Bronchiectasis to illustrate oxygen replacement and artificial pneumothorax. 2. A case of Diabetes with Acidosis to illustrate the benefit which might follow "oatmeal cure."

Mr. LEWIS BEESLY showed a girl aged 2 years. She had had tuberculous dactylitis when 9 months old, with abscess formation, and complete recovery after removal of sequestra. Five months later a painless enlargement around the left ulna developed. Tuberculous osteomyelitis in the proximal half of the diaphysis was diagnosed. Subperiosteal resection was performed on July 14th, 1913; primary union took place, and there had been no further sign of tuberculosis.

Mr. A. A. SCOT SKIRVING showed a man, aged 31 years, after very extensive operation four months ago for Squamous Epithelioma of the Left Upper Jaw. Owing to implication of the skin of the cheek no flap could be made use of. Accordingly the parts involved (including the left eye and part of the nose) were removed *en masse*, with the result that a huge open cavity was left. Though smaller than at first, the cavity was still very large. A plastic operation to restore the mouth had been done, and a further plastic operation to close the cavity was shortly to be carried out by means of a flap from the scalp or from the left upper arm. Much help had been obtained at the operation from the intratracheal method of giving the anæsthetic and from preliminary ligature of the external carotid.

EDINBURGH OBSTETRICAL SOCIETY.

Gift of a Presidential Chair.—Stillbirths Registration.

A MEETING of this society was held on May 13th, Sir J. HALLIDAY CROOM, the President, being in the chair.

The PRESIDENT intimated the gift of a Presidential Chair from Dr. H. M. Church; it is decorated with the crest and motto of the society—viz., the beautiful head of Lucina (or Juno), the goddess who presided over marriage and childbirth, with an olive branch and young olives on either side, intertwined with the motto "Floreat Lucina." The society was founded in 1840.—Dr. CHURCH was very cordially thanked for his gift and made a suitable reply.

Dr. J. W. **BALLANTYNE** read a paper on Stillbirths Registration at the meeting of the society in March.[1] The subject was referred to the council for consideration and report. The council recommended the following modifications of Dr. Ballantyne's conclusions:—

1. That, in view of the existing confusion in the terminology of stillbirths and allied states, an attempt to reach uniformity of definition should be made.

2. That an Ante-natal Deaths ("Still-births") Registration Act is greatly needed in this country.

3. That the definitions of dead-birth, live-birth, still-birth, and abortion should be so constructed as to be in accordance with the physiology of the time of life dealt with. The following definitions are suggested:—

(*a*) For *dead-birth*—the complete expulsion from the maternal birth-canals of a child which, during or before birth, has lost the characters of ante-natal life (heart-beat, arterial pulsation, and movement).

(*b*) For *live-birth*—the complete expulsion from the maternal birth-canals of a child which, whilst it loses pulsation in the cord, adds *on to the other characters of ante-natal life* the special sign of post-natal vitality—viz., pulmonary respiration.

(*c*) For *still-birth*—the complete expulsion from the maternal birth-canals of a child which, whilst continuing to exhibit one or more of the signs of ante-natal life (heart-beat, arterial pulsation, movement), fails for a time to assume that of post-natal life (pulmonary respiration), and then either loses even the characters of ante-natal life, or is successfully resuscitated (*transanimated*), *and assumes those of post-natal existence.*

(*d*) For *abortion* or miscarriage—the termination of ante-natal life (by the expulsion of the uterine contents) before the end of the sixth month. A *premature birth* is expulsion of the uterine contents after the sixth month, but before the full term, and it may be a dead-birth, a live-birth, or a still-birth.

Dr. W. **LESLIE MACKENZIE** (Local Government Board) said the Notification of Births Act (1907) simply spoke of notifying the birth of a child, and included every kind of birth. Dr. A. K. Chalmers, medical officer of health of Glasgow, had found it of the greatest value in one respect with regard to stillbirths, and he had supplemented it with the free use of the Wassermann reaction. In Scotland, although the Act had not been adopted under pressure to any great extent by the local authorities, yet the actual population under notification was rather more than 50 per cent.; that was, nearly 2½ millions of people were under notification. He felt that three things hung together: the Notification of Births Act, the proper regulation of midwives, and the whole question of infant mortality. The Local Government Board had practically determined that where the Notification of Births Act was not adopted to have it done by themselves. This Act, on the whole, in spite of the unfortunate exception that the medical profession were not paid for the duties required of them, had been fairly satisfactory. There was a danger of confusion in accepting Dr. Ballantyne's definition of stillbirths seeing that that term had such a deep-rooted association with a dead-born child. Personally he would risk the confusion and raise the standard of the practitioner's knowledge. A vast amount of statistics would be obtained, and even if limited would be of great value in the hands of good medical officers of health. Miss Margaret Bousfield, of the National Women's Guild, in a pamphlet laid stress on the compulsory notification of births and the urgent need of attention to stillbirths.

Dr. J. **CRAUFURD DUNLOP** (superintendent of the Statistical Department, Register House) said he was absolutely at one with Dr. Ballantyne up to a certain point. He quite agreed that more accurate definition was required, and interesting and important information might be got, but he disagreed as to the method of getting it. He disagreed about the use of registration for the purpose instead of notification. Vital statistics were a by-product, but were not the primary function of registration. Registration was producing a register for civil rights and records which were preserved and kept for all time. It would be of no interest to anyone 50 years hence that a father or mother had a dead baby. Registration would produce excellent statistics, but these could be got equally well by compulsory notification. One must look at it from the practical aspect. Registration was done by registrars who in Scotland were a very intelligent set of men, but they had no medical knowledge. They would not know whether a child had lived or not, or the duration of pregnancy; they could not question the mothers about their menstruation. The duties were beyond the capabilities of a registrar, and the registration of these cases did not fit in with the established system of registration in Scotland. He considered that if a child capable of re-animation died it should remain on the stillbirths register, and if it lived it should go on to the live register. The principal object of notification was statistical information in order that the medical officer of health might take action and supervise the cases. The medical officer of health should be directly notified, and it should be done in secret. The medical officer of health had the technical knowledge necessary to appreciate it. Notification would not complicate the present good system of national registration, which system primarily was to establish civil rights.

Professor H. **HARVEY LITTLEJOHN** said the chief function of statistics was not purely civil. The registration of vital statistics had been of the greatest importance in combating disease in various forms; nothing more valuable had been done in the cause of preventive medicine. With regard to the paper, what they wanted to know was whether these were dead-born children. He did not know whether medical men wanted an abortion to be notified. They wanted to know whether a child died from constitutional disease (syphilis) or from some accident. He did not think one could get that information. One could not make a distinction if the child died a week before or an hour before birth. The stillborn child was one who was born without giving any obvious sign of life, the heart was still beating, only the respiration was wanting, it was easily revived and came to life. What was to be gained by knowing the child was silent-born? There were dead-born children and live-born children, and he did not think any more was required.

Dr. D. **BERRY HART** said the object of registration was to gain information as to the health of the nation. They wanted to find out the influence of syphilis in producing premature labours and stillbirths; they wanted also to find out the influence of rickets in producing stillbirths from narrowing of the pelvis. Comparison in future years would show whether the national health was improving, and rickets and syphilis were becoming less. He was a little doubtful about the registration of stillbirths; it was a refinement. As many statistics as possible should be obtained, but they should not ask for stillbirths but for live-born and dead-born. He thought the statistics of abortions would be absolutely worthless if they were asked for.

Dr. G. **KEPPIE PATERSON** considered this notification would be far better to go through the hands of the medical officer of health than through those of the registrar; it should be made compulsory all over the country, and to be of value it must be secret between the medical attendant and the medical officer of health. Dr. Ballantyne had defined an ideal scheme to obtain a wider knowledge for the sake of national eugenics. The definitions were ideal, but some difficulty might arise in the notification. If compulsory, some of it would require to be done by midwives. In maternities and in dispensary practice where they could deal easily with a patient they might get important information to notify; but in private practice it might cause a great deal of trouble if the cause of the stillbirth or dead-birth was hereditary. Many were due to syphilis. This was recognised also in the evidence before the Commission on Venereal Diseases, and yet the majority of those with experience were against the compulsory notification of syphilis. If a medical man was compelled to put in the cause of a dead-birth as syphilis, it might involve him in a great deal of trouble in his practice. The husbands mostly deny it. What was one, then, to do? What was to be done to find out the cause? The husband would not submit to a Wassermann test, and what was to be done? If the cause of dead-births and stillbirths was not to be put in, of how much value were these statistics? It would always be a step in the right direction, but it would involve a very serious difficulty. Many medical men would never enter the cause at all or would insert it in such a way as to be useless.

Dr. A. H. F. **BARBOUR** agreed that it would be well to have "abortions" registered so as to show the tendency to diminution; he did not think, however, they would get any statistics because it would be necessary to show that these abortions occurred in the same family, and also that the frequency of abortion showed that it was related to infection. Premature birth resolved itself into the practical question whether the child was alive or not. The time stated of six months might be better extended to the birth of a viable child. What one wanted to get at was the health of the community. In order to do that two classes of cases must be distinguished—one class in which the child died in the uterus and was expelled subsequently, at what time it did not matter; and another class in which the death of the child occurred during the process of labour. In dealing with the latter the subject became complicated. In the first class there was some constitutional cause affecting the health of the community, while in the second one was at once brought up against the possible bad management of the labour on the part of the midwife or medical man. The management of labour was improving; there was now a better class of midwives. If one could prove that the child died during labour, then one was faced with a number of other causes which had nothing to do with the community. He considered it important to get information as to whether the child died in labour or not.

---

[1] THE LANCET, March 28th, 1914, p. 886.

Dr. JAMES RITCHIE considered for scientific purposes it would be desirable to have compulsory notification of all pregnancies and abortions, but he did not think it was possible; they would be so incomplete as to be really impracticable. The more vital statistics that could be got the better for health. Notifications should be compulsory after 28 weeks of gestation and made to the medical officer of health, who would collect the statistics that were described and then forward them to the Local Government Board. Medical men and midwives should be paid for it.

Dr. J. HAIG FERGUSON said the paper from a scientific point of view was all that was to be desired, but from a practical point of view it was far too elaborate for any useful practical purpose. From the popular point of view a stillbirth meant a deadbirth. That was seen in the papers every day, and they could not get rid of it.

Dr. J. LAMOND LACKIE could see no reason whatever for registering stillbirths, but all cases of deadborn children ought to be registered; and a difference should be made with regard to ante-natal deaths and stillbirths.

Dr. BALLANTYNE, in reply, said there was an error in the heading, it should be ante-natal deaths (commonly known as stillbirths) or with stillbirths in inverted commas. The question of the practical value of such a measure was the same criticism as applied to all registration and notification such as in infectious diseases and tuberculosis. It might be optional at first to put in the cause, and after some years the insertion of the cause could be made compulsory after the profession had become accustomed to it. He considered that it would be quite possible to get a good result under notification; he could see difficulties with the registration. He was not conscious that he had asked that stillbirths should be separately notified. There was an actual difference in definition between deadbirth and stillbirth. If so, were they to accept the popular opinion? He considered respiration as the best sign of post-natal life; movement was not as it took place in the uterus. The subject they were striving for was the future health of the nation. They wanted to know about the congenital causes of deaths occurring within a few months of birth. He wished to push back the date of viability, as with the better class of incubator the fœtus had been made to survive at an earlier age.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Congenital Pyloric Stenosis.—Thrombosis of the Internal Jugular Vein.—Operative Treatment of Goitre.

A MEETING of this section was held on May 8th, Mr. A. BLAYNEY being in the chair.

Mr. C. A. K. BALL showed a case of Congenital Pyloric Stenosis in an infant aged 7 weeks treated by gastro-enterostomy. He said that three weeks ago he was called to the hospital to see a child whose bowels had not moved for ten days. The child from birth was said to be healthy. Oil and enemata had no effect, and it vomited when fed, and passed no urine. It was, therefore, considered that there must be obstruction high up, and as the child was in a very serious condition it was decided to open the abdomen at once. The pylorus was found to be greatly enlarged, and this enlargement appeared to extend into the duodenum. The swelling was hard and smooth on the surface. Plastic operation was not possible, as the obstruction seemed to be complete and was very hard. It being apparent that the child would die if nothing was done, it was decided to do a gastro-enterostomy. No difficulty presented itself in doing the operation. The child was very weak for two or three days, but in about 24 hours after operation the bowels moved, and three weeks after the operation it was quite strong and healthy.

Mr. W. PEARSON showed a specimen of Thrombosis of the Internal Jugular Vein removed from a boy, aged 14, who suffered from mastoiditis. One side had been operated upon, and while waiting to have the opposite side done he developed a high temperature, a foul-coated tongue, and rapid pulse. The optic discs were normal, and no mental symptoms were apparent. There was no tenderness over the mastoid, but there was extreme tenderness down the neck over the course of the jugular vein. It was obviously a case of infection of the lateral sinus. He described the operation which was carried out. A clot tapering off to the lower end was discovered. This clot extended down into the innominate vein. Thrombosis was present in all the branches round the vein. The vein was divided at the posterior belly of the omohyoid, and it was determined to remove the clot which was in the vein. A radical mastoid operation was then done, and round the sinus pus was found. Saline was irrigated through, the neck wound was drained, and the sinus packed with gauze. He considered that the infection took place through the lymphatics. The case was not much improved by the operation, and terminated fatally on the fourth day.

Mr. D. KENNEDY discussed the indications for Operation in Goitre and Exophthalmic Goitre, and gave details of the treatment as carried out by him. He advocated early operation in all cases, and always employed general anæsthesia.—Mr. BLAYNEY said he thought the question of operation in cases of exophthalmic goitre was not so easy. He suggested a classification into two distinct types. A patient might have had an enlarged thyroid for years, and in such a case the increase in the rapidity of the pulse was generally moderate and the degree of hyperthyroidism was not great, and with such a patient the operation was attended with no more than the ordinary risk. On the other hand, in cases where the gland was vascular, where there was great rapidity in the pulse and the skin was constantly moist, and there was evidence of sugar in the urine, he considered operation dangerous. If the operator treated cases of the first type it would be quite possible for him to produce good statistics, but in the latter class of cases he thought the death-rate would be higher than 4 per cent. He pointed out that Mayo recommended that the latter class of cases should not be touched. His own experience of exophthalmic goitre was confined to the first type of case.—Sir JOHN LENTAIGNE said he agreed with Mr. Blayney that there were cases of exophthalmic goitre which should be well considered before operation was undertaken, and that there were cases of another type not much more troublesome than cases of simple goitre. He considered that the use of local anæsthesia could hardly be foregone, and that in cases in which there was great dyspnœa etherisation appeared to increase the size of the goitre and thus increase the danger. He suggested that where local anæsthesia was employed a screen should be used to prevent the patient from seeing the blood. He considered that the disease was becoming more common than it was years ago.—Dr. W. M. CROFTON said he did not think the physician was so hopeless in the treatment of these cases as Mr. Kennedy seemed to suggest. If the tumours were causing dyspnœa surgical interference should, of course, be sought, but he had seen several cases in which the exhibition of pituitary and suprarenal extract had made the goitre disappear.—Mr. W. PEARSON said he agreed that sometimes medical treatment in those cases was efficient, but there could be no doubt that medical treatment would not remove a cyst from the thyroid. He disagreed that the physician was the best person to decide when a patient should be operated upon, as there was a danger that he might be opposed to operation until such time as the kidneys, heart, and liver had undergone permanent organic changes, and this should not be waited upon before the operation was undertaken. In all early cases, where the symptoms were mild, he suggested that medical treatment should be given a trial. If a case in which there was no glandular enlargement did not respond to medical treatment, he considered that the right surgical treatment would be pole ligation instead of extirpation; but ligation of the arteries alone would not, he thought, suffice. Post-operative treatment he looked upon as important, the most important thing being to give the patient large quantities of saline for the first 48 hours. Acute thyroidism coming on after operation he thought was largely due to rough handling during the operation, and not to absorption from the cut surface of the gland.—Mr. KENNEDY, replying, said he never advocated operation in all cases of exophthalmic goitre, although he suggested that if all cases were operated upon early no difficulty would be experienced. He thought it was generally admitted that when medicinal means were successful the success was due to the rest rather than to the drugs used. One of the motives of his paper was to call the attention of physicians to the good results of operative treatment in these cases. He considered that the adhesion of the lobe to the trachea was a common reason for dyspnœa. He agreed that post-operative hyperthyroidism was due to rough handling during the operation.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Devon and Exeter Hospital on May 8th, Mr. Ransom Pickard, the President, being in the chair.—Dr. R. V. Solly showed: 1. A case of Actinomycosis of the Jaw in which he had combined vaccine treatment with iodide of potash, the former seeming to have greatly influenced the cure of the case. 2. A girl with Hypertrophy of the Left Side of the Trunk and of the Left Arm and Leg, with lack of power on this side and lowered temperature. Dr. Solly suggested the pituitary body as a possible source of the condition. 3. Cast of Œsophagus from a case of fibrinous inflammation of the œsophagus. 4. Alveolar Sarcoma of Skin. 5. Spleen from case of spleno-medullary leucocythæmia, together with blood films from the same.—Mr. Russell Coombe showed a case of Mucocele of Appendix.—Mr. A. L. Candler read a paper entitled "Experimental Proof of the Value of a Mask over the Surgeon's Mouth during Operations." He said he had experimented with B. prodigiosus for the reasons (1) that it was absent from ordinary air and from the mouth; (2) that it grew in red colonies and therefore could easily be distinguished from other organisms macroscopically; and (3) that it was non-pathogenic. These bacilli were added to water until the mixture was turbid and slightly pink, and Mr. Candler then filled his mouth with the suspensions thus formed, gargled, and immediately proceeded to either breathe, speak, cough, or sneeze, without or with a mask, over a series of sterile agar plates. Any red colonies of micro-organisms found on the plates after incubation must therefore have come from within his mouth. The plates used were of agar in Petri dishes of a diameter of 3½ inches, and the mouth was held in all cases 18 inches away from the plate. Each experiment was conducted in a separate room in order to avoid any air infection of the plate from a previous experiment. The mask used was of fine butter muslin reinforced with plain gauze over the nostrils and mouth. In some tests six layers of gauze were used and in others eight. A table prepared from the results showed that with quiet breathing and speaking no B. prodigiosi left the mouth. Coughing for two minutes caused only a few bacilli to be expelled, and these were controlled by a mask of eight layers of gauze, four being insufficient. One sneeze produced 130 colonies in a circle of 3½ inches at a distance of 18 inches, and Mr. Candler had found even eight layers of gauze insufficient to keep back an organism during prolonged sneezing, although, of course, there was reduction in the infection. Mr. Candler said that in his experiments the mask had been subjected to far more severe tests than would occur in surgical practice, and therefore such a mask was efficient and useful to the surgeon, for with it he could speak, clear his throat, and even cough without fear of infecting the wound. He recognised that objection to masks was sometimes raised by surgeons who wore spectacles, but in the pattern he described (and showed) to the meeting the disadvantages were obviated. Finally, Mr. Candler hoped that he had shown that a mask, such as he had described, was not only necessary, but efficient, and a very safe guard to the patient during surgical operations.—In the discussion which followed the President said he had so far hesitated from using a mask in operations upon the eye, which were usually of brief duration.—Dr. W. Gordon alluded to the carrying power of a sneeze and its importance both from a medical and a surgical point of view.—Mr. Robert A. Worthington was confirmed in his own mind that masks were unnecessary. He excepted operations on bone and in the neighbourhood of joints.—Mr. Russell Coombe adopted a mask in heavy operations, such as removal of ovarian cysts, where free perspiration was likely to be caused to the surgeon.—Mr. Candler, in his reply, said that everything should be done with a view to diminishing infection of wounds and making for the comfort of the patient. If surgeons admitted the necessity of a mask in bone operations it showed a mistrust of their own mouths, which went to support the case he had sought to prove.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held in Queen's University, Belfast, on May 14th, Mr. A. B Mitchell, the President, being in the chair.—Sir John Byers showed a mounted specimen of the Uterus, Ovaries, and Tubes, injected after the Spalteholtz method, by which, through transmitted light, the various parts were clearly displayed, especially the arteries and veins, in a way that no other method yet devised could at all equal. He also exhibited a model of a Female Pelvis with the various organs and structures *in situ* which, he said, was of great value in clinical teaching, as it enabled students to recognise better the landmarks.—Mr. R. J. Johnstone showed a Uterus which he had removed by Wertheim's method for a malignant adenoma from a married woman. He also exhibited an early Ovum from a case of extra-uterine pregnancy, and a very large Tuberculous Pyosalpinx.—Dr. J. M. Gibson read a paper on the Experimental Production of Heart-block. A frog was perfused with a weak solution of yohimbin, a drug obtained from a plant in Central Africa, which caused heart-block by acting on the auriculo-ventricular bundles of His. After a time adrenal solution—which is a stimulant—was perfused, and gradually the condition of heart-block passed off. Under both conditions Dr. J. E. MacIlwaine took records and electrocardiograms, which were shown and compared with the condition of heart-block as it attacks the human being, the various tracings being very much alike.—Professor T. H. Milroy gave an account of hydrogen ion concentration changes in the blood during apnœa, and he and Dr. Gibson also gave an account of changes in the reaction of certain of the body fluids—blood, gastric juice, and milk.—An interesting discussion followed, in which Professor J. A. Lindsay, Dr. J. L. Rentoul, Professor Milroy, Sir John Byers, Dr. MacIlwaine, and the President took part.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 1st, Mr. A. Ernest Maylard, the President, being in the chair.—Dr. George A. Allan demonstrated a case of Complete Heart-block in a patient who for the past ten months had been subject at frequent intervals to fainting fits with loss of consciousness. These fits were associated with the inception of a very slow ventricular rhythm, varying from 20 to 40 per minute, and dependent on complete heart-block. No other manifestations of the Stokes-Adams syndrome, such as general convulsions, were present. The Wassermann and luetin tests were positive, and gummata were present on the iris. Polygraph tracings showed complete dissociation of auricular and ventricular contractions, the former numbering 75 to 96 and the latter 22 to 27 per minute.—Professor T. K. Monro, Dr. G. H. Edington, and Dr. J. Shaw Dunn described a case of malignant ganglio-neuroma of the suprarenal in a boy aged 3½ years, and gave a microscopic and lantern demonstration. Post-mortem examination showed a tumour the size of a large orange in the left suprarenal body with metastatic deposits in the retroperitoneal, mesenteric, mediastinal, cervical and inguinal glands, and in the bones of the skull and the ribs. Part of the tumour was firm and pale and was composed of mature nervous tissue—ganglion cells and fibres; part was soft and obviously malignant, and was composed of smaller cells and fibrillæ corresponding to the embryonic nerve cells and fibrillæ which form the sympathetic nervous system in normal development.—Professor Monro and Dr. G. Haswell Wilson reported a case of Malignant Tumour of the Neck which involved the spine and the cervical and brachial plexuses.—Dr. Edington showed a youth, aged 16, on whom he had operated on Oct. 16th last for laceration of the right kidney. The lad had sustained the injury by falling on the deck of a torpedo boat and striking his back against a fixed ring projecting from the deck. Laparotomy by transverse incision was performed, and the right kidney was found in two completely separated parts and was removed. The left kidney appeared normal. Recovery was excellent.—Dr. Edington and Dr. Dunn showed a Partially Pyonephrotic Kidney, with double ureter and pelvis. The specimen was obtained from a married woman, aged 33, who had a history of pain in the right side with bilious vomiting occurring at intervals for the past six years. Latterly there had been swelling in the right flank disappearing coincidently with free flow of muddy urine; the urine contained pus. The patient sweated at night and had lost flesh. Nephrectomy was performed through a transverse incision through the anterior abdominal wall; the other kidney appeared normal, and the patient made a good recovery. The excised kidney proved to have a double ureter and pelvis; the pyonephrosis affected the lower pelvis. The upper ureter led to a normal pelvis and kidney perched on the upper surface of the cyst. There was nothing to indicate the cause of development of the obstruction; no calculi were found in the pelves or ureters.—Mr. Henry Rutherfurd showed: 1. A Colon with Ulceration and Perforation of the Root of Volvulus of Sigmoid after operation for reduction. The patient was a man aged 65, bedridden and paralysed. 2. The parts concerned in a Fracture of the Femur by direct violence, where gangrene resulted from pressure by the lower fragment on the femoral artery and vein at the lower end of Hunter's canal. The vessels were not torn but had been hooked round to the outer side of the femur by displacement of the lower fragment. 3. Water-colour drawing of a case of Gangrene of the Penis in a man aged 32, from causes so far unexplained. There was no evidence of gonorrhœal infection. 4. A fresh specimen of Chorion-epithelioma of the Uterus.

Reviews and Notices of Books.

La Geographia Medica de la Peninsula Iberica.

By Dr. PH. HAUSER. Three volumes. Madrid: Eduardo Arias. 1913. Pp. 633 + 611 + 364.

IN his preface to this monumental work on the demography of the Iberian Peninsula Dr. Hauser speaks of Spain as his adopted country, and alludes with feeling to the 40 years he has spent there in professional and literary work. Spain has reason to be grateful to her naturalised son, for Dr. Hauser has striven with unwearied energy and conspicuous literary ability to convince the Spanish authorities, national and municipal, of the appalling amount of mortality and unnecessary suffering directly due to apathy in matters of hygiene and sanitation, and of the urgent necessity for sanitary reform and for efforts to provide a pure and abundant water-supply in the many towns and districts in which the water at present available is both scanty and contaminated. In 1883 Dr. Hauser published his "Estudios Medico-topographicos y Sociales de Sevilla" in two volumes, and followed later, in 1903, with a similar work on Madrid, "Madrid bajo el Punto de Vista Medico-social."[1] Again, in 1887 there appeared from Dr. Hauser's pen a work in three volumes based on the experiences afforded by the great cholera epidemic in Spain in 1885, "Estudios Epidemiologicos Relativos a la Etiologia y Profilaxia del Colera." The interest excited by these essays in demography, both in Spain and beyond her borders, inspired Dr. Hauser with the design of dealing fully with the climatology and medical geography of Spain and Portugal, and the present work is the result.

The first volume is devoted chiefly to a detailed study of the climatology of the peninsula. Among the various factors determining climate Dr. Hauser rightly regards physical geography as of fundamental importance, and accordingly he devotes Part I. of the volume, comprising Chapters I. to VII., to a description of the general surface contour of the peninsula, its mountain and river systems, its geology, and the geotectonic evolution of the peninsular mass. All this might sound more fitted to a technical work on geography than to a medical treatise; its bearing, however, on the lives and health of the human inhabitants of the regions described is never lost sight of. Part I. closes with an interesting chapter on the mineral waters of Spain in relation to the evolution and geological structure of the Peninsula, in which the author marshals a mass of facts which help towards an understanding of the relation existing between the chemical and mineralogical character, physical action, and temperature of the various medicinal waters and the geology of the districts they traverse and in which they issue to the surface. The second part of Vol. I. deals with climatology proper, opening with a chapter on the influence of the soil on climate. The combined influence of the soil and of atmospheric conditions on the flora of the peninsula is next discussed, this section containing an interesting description of the steppes of Spain, which with Hungary is the only European country outside Russia possessing true steppes. In the remaining chapters of Part II. rainfall, humidity, evaporation, and atmospheric pressure in the above zones are dealt with, and the section closes with a brief account of the powerful effects of solar radiation and a final chapter on the volcanic areas of Spain and on earthquake action. Part III. deals with the ethnic evolution of the Iberian peninsula from prehistoric to modern times and the bearing thereon of its geological development, an interesting account being given of the anthropometry of the different zones and the distribution over the peninsula of brachycephalic and dolichocephalic types. The volume is enriched by a large number of excellent maps and plans, and a series of elaborate meteorological charts.

The second volume is devoted to demography proper. Part I. deals with the movement of population in Spain and Portugal, with birth, marriage, and mortality rates *en gros*, and with emigration, and concludes with an interesting account of the beautiful but almost uninhabited region, the Alpujarras, and of Las Hurdes, an isolated district in the centre of Spain, whose miserable inhabitants live under conditions of unimaginable squalor, compared with which the worst conditions prevailing in the west of Ireland in the worst times of last century can be regarded only as luxurious. Part II. deals with the hygienic and sanitary conditions of the towns and provinces of Spain, and gives a detailed survey of the vital statistics of Spain as regards the chief infective fevers during the years 1900–06. This survey is followed by chapters on tuberculosis, cancer, and paludism, which are of special interest.

The third volume deals with the slowly developing infections—leprosy, pellagra, syphilis, goitre, and ankylostomiasis—and discusses the distribution of arthritism and alcoholism, and the influence of the physico-chemical characters of the soil of certain regions in Spain in the etiology of such diseases as cholera, enteric fever, rickets, and arterio-sclerosis, with its pendant cerebral hæmorrhage. Several chapters are devoted to the distribution of disease throughout the peninsula, as shown in tables of mortality, and the work concludes with a full and interesting account of suicide in Spain.

---

[1] Reviewed at length in THE LANCET, Feb. 21st, 1903, p. 523.

We cannot speak too highly of Dr. Hauser's work as a whole; it is a monument of enlightened industry. The work, moreover, is admirably got up, and both the printing and the reproduction of maps, plans, charts, and tables are deserving of every praise.

Handbuch der Tuberkulose.

In fünf Bänden. Herausgegeben von L. BRAUER, G. SCHRÖDER, F. BLUMENFELD. Vol. I. With 116 illustrations, curves, coloured plates, and photographs. Leipzig: J. Barth. 1914. Pp. viii. + 792. Price, paper, 35 marks; bound, 37 marks.

TEN years ago Schröder and Blumenfeld published their well-known text-book on the treatment of chronic phthisis. They have decided to issue its second edition in the form of a massive "Handbook of Tuberculosis" in five volumes, of which the first has just appeared. In addition to the three editors, 45 contributors are mentioned on the title-page, almost all of them Germans.

The first volume is divided into two sections, the first given up to general considerations, the second beginning the description of pulmonary tuberculosis. There are nine contributors to the first section, which leads off with a historical review of tuberculosis by Predöhl, perhaps a rather perfunctory account of a subject that this well-known historian of tuberculosis might have made much more illuminating. The pathological anatomy of the disease is described by Tendeloo; the tubercle bacillus itself is the subject of a very thorough article of 160 pages by Much, who also contributes 94 pages on the subject of immunity to tuberculosis. He agrees with Römer in believing that the tuberculous infection during infancy or childhood, which is so common as to be an inevitable incident of life in civilised countries, affords a most valuable degree of acquired immunity to subsequent infections with tubercle bacilli. Inherited immunity to tuberculosis, handed on from mother to child, he believes to be of but trifling and transient importance. Some account of tuberculosis in animals and the way in which it must be combated is contributed by C. Dammann, and this article contains a quantity of interesting information usually to be met with only in veterinary works. In the second section of the volume are half a dozen articles on various aspects of the diagnosis of pulmonary tuberculosis and on the clinical forms of this disease. An excellent account of the clinical significance of the various tuberculin reactions is given by J. Ritter, who comes to the conclusion that the results yielded by these tests are often not in themselves enough to enable the question, "Does the patient require treatment?" to be answered; it is often necessary to keep the patient under observation for a time in order that clinical evidence as to his condition may be obtained, and his social condition must also be taken into careful consideration.

It is not possible in a short review to do justice to the many excellences of this encyclopædic work. It is well written, though naturally somewhat uneven in merit; countless references to the literature are given; the illustrations are well chosen, and many of them are very good. Full justice is done throughout to the work of the German school of medicine and pathology; the French, American, and English writers on tuberculosis, though not wholly neglected, appear generally to receive scantier notice in this volume than they deserve. The "Handbook" promises to be by far the most complete account of tuberculosis in existence.

Defective Ocular Movements and their Diagnosis.

By E. and M. LANDOLT (Paris). Translated by ALFRED ROEMMELE, M.B., Ch.B. Glasg., and ELMORE W. BREWERTON, F.R.C.S. Eng. London: Henry Frowde and Hodder and Stoughton. 1913. Pp 99. Price 6s. net.

Dr. E. Landolt has long been an authority on the ocular muscles. He has repeatedly written on the subject both in French and German. In this small volume, in which he has associated with his son, Dr. M. Landolt, a lucid and accurate résumé of the chief facts of the anatomy, physiology, and derangements of the extrinsic ocular muscles is given. So small a book devoted to so large a subject can be little more than a notebook of the more prominent facts, but, as is often the case in French works, it reads less like a précis than might be expected. We note that very little space is allotted to concomitant strabismus, and such as it is, the reference is chiefly to the differential diagnosis from paralytic strabismus.

This brochure is, indeed, so condensed that it can be commended rather as a useful reference book than as a guide to the student. A sound diagnosis in the cases met with clinically cannot be formed without an accurate knowledge of the symptoms and signs of paralysis of individual muscles, and such knowledge is concisely and clearly stated here. Clinical experience, however, shows that what may be called the academic paralyses occur relatively seldom and offer little difficulty. The really difficult cases are those of partial paralysis, often showing an unexpected grouping of muscles. When these are combined with latent squints, rendered manifest by the abnormal paresis, great difficulty may be experienced, and it is to be regretted that writers on the subject do not pay more attention to these, which are perhaps the most important cases.

The book has been well translated, but is not free from misprints. A table of contents would have been advantageous, for the arrangement of the sections is somewhat unusual.

Manual of Obstetrics.

By JOHN OSBORN POLAK, M.Sc., M.D., Professor of Obstetrics and Gynæcology in the Long Island College Hospital; Professor of Obstetrics, Dartmouth Medical School, &c. London: D. Appleton and Company. 1914. Pp. 468. Price 12s. 6d. net.

THE object of this book is to place the essential facts and principles of obstetrics within the easy grasp of the student. It is intended as a systematic introduction to more elaborate treatises, and as the author points out in his preface his experience has shown him that if the student can be made to master the elements of a subject, complete and systematic knowledge of it becomes a matter of easy growth. Practical topics have received most attention and emphasis is given to them by the use of italics.

In the chapter on reproduction we notice that the statement is made that some of the male sex cells acquire two accessory chromosomes during maturation: these spermatozoa give rise to female offspring, while the spermatozoa which develop without the accessory chromosomes give rise to male offspring. We were not aware that this fact had been definitely proved in man, although it has been shown to be probably the case in some other animals. In a book which is intended to be primarily practical it seems rather anomalous to devote nearly 80 pages to anatomy and development and some five pages to a list of anomalies.

The section on the management of labour is well written and full. We cannot, however, agree that the membranes should be preserved until they protrude at the vulvar orifice; when this occurs it practically always means that the amnion and chorion have been separated from one another, and this certainly encourages retention of a portion of the chorion. Nothing is said of the danger to the fœtus of giving morphia and scopolamine for the production of "Dämmerschlaf." In the section on the treatment of labour in flat pelves with a conjugate of 2¾ inches or less, Professor Polak says that at full term Cæsarean section or the Porro operation is indicated; we presume he really means supravaginal hysterectomy after Cæsarean section, as we note that on p. 411 he points out that the classical Porro operation is now practically superseded by the modern supravaginal amputation. The section on the treatment of placenta prævia is entirely in accord with the best English teaching at the present time, and it is interesting to note that the author is not very enamoured of the treatment by Cæsarean section. In any condition in which it is necessary rapidly to terminate the pregnancy and the cervix is undilated and rigid, vaginal Cæsarean section is recommended. In the prevention of ophthalmia neonatorum the fact that when the eyes are properly treated with silver nitrate or argyrol the immunity is practically absolute is well borne out by the experience during the past year of one of the largest extern maternities in London. During the year only one case of ophthalmia occurred, and in that instance the student attending the case had forgotten his bottle of silver nitrate.

This is a good book, much better than many more pretentious manuals, and the teaching is practical and based on sound principles.

Materia Medica, Pharmacology, Therapeutics, Prescription Writing, for Students and Practitioners.

By W. A. BASTEDO. London: W. B. Saunders Company. 1913. Pp. 602, with 60 figures. Price 15*s.* net.

THIS workmanlike volume is an adaptation, for the most part, of lectures delivered at Columbia University. It is divided into three parts. Part I. gives an introduction to the study of pharmacology, its objects, methods, and scope. Part II., occupying 470 pages, is devoted to the consideration of all the various drugs in common use, grouped according to their special therapeutic properties. Lucid descriptions of the way in which the various drugs act are given, particularly from the point of view of experimental physiology. An excellent characteristic of the book is the fulness with which the more important drugs are considered, such as digitalis, nux vomica, and belladonna. The author is thoroughly up to date, and offers his readers good résumés of current views upon the actions of these and many other drugs. He is perhaps a little severe on smokers, quoting with apparent approval the highly coloured statement that "it is generally conceded that the use of tobacco by college students is closely associated with idleness, lack of ambition, lack of application, and low scholarship." Part III. is an account of how to write prescriptions. The author advises that these should be written in Latin. The United States Pharmacopœia, and the National Formulary ("N.F.") of the American Pharmaceutical Association, which attempts to standardise some of the non-pharmacopœial preparations commonly used in America, are naturally the pharmaceutical authorities to which Dr. Bastedo chiefly refers.

The book is well got up and well printed; it has an excellent index and but few misprints. It may be pointed out, however, that the spellings "anidrotics" and "anhydrotics" (pp. 386, 565) are both incorrect, and therefore inferior to "anhidrotics," as applied to remedies designed to diminish sweating. Dr. Bastedo's book is not written with the object of getting students through formal examinations; it contains a large amount of sound practical advice, and may be recommended to the attention of all practitioners of medicine who wish to know what drugs to give and why to give them.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India.

New Series, No. 60. *Studies on the Mouth Parts and Sucking Apparatus of the Blood-sucking Diptera.* No. 4. By Captain F. W. CRAGG, M.D., I.M.S. Calcutta: Government Printing Department. 1913. Pp. 78. Price 1*s.* 9*d.*, or Rs. 1.2.

WE have recently noticed other contributions to this useful series, and among the authors of those contributions Captain Cragg has appeared more than once. The present memoir is the fourth of the "studies," and deals with the comparative anatomy of the proboscis in the blood-sucking Muscidæ, with the genera Musca, Philæmatomyia, Stomoxys, Hæmatobia, Hyperosia, and Glossina. The text is illustrated by five plates in which the mouth parts are clearly displayed in large and therefore readily intelligible figures. But the work is of a purely technical character, serving as a contribution to anatomical entomology; it deals with more general matters only in an incidental way. The whole question, however, of the habits of these flies, so closely associated with the transference of parasitical disease, cannot be entirely evaded, even in the most technical of memoirs of the character of that which we notice here. And in fact Captain Cragg has a not uninteresting section upon the development of the blood-sucking mode of life in the Muscidæ.

He points out that the non-biting flies of the genus Musca are mostly omnivorous in habit, and particularly affect animal juices; it is a matter of common observation that they are especially attracted by wounds, upon the exudations from which they feed; they will also form temporary associations with actual blood-sucking flies, taking advantage of the wounds which the latter have caused and filling themselves with the flowing blood after the Hæmatobia or other biting form has become replete and flown away. Furthermore, it seems possible that the "teeth" upon the prestomium may at least clear away a clot and permit access to the blood or other animal juice beneath. It seems therefore reasonable to suppose that an accentuation of these teeth combined with other structural changes in the mouth parts may have succeeded to such habits, and in course of time have converted an omnivorous muscid to a purely blood-sucking form. It would follow from this that the parasites originally belong to the flies and not to the vertebrates which the modified forms bite.

Physiological Histology of Man and Mammalian Animals.

Illustrated by Microscopic Preparations, with Explanatory Text and Drawings. By Professor Dr. FR. SIGMUND, Teschen (Austria). English edition by C. LOVATT EVANS, University College, London. In ten parts, each consisting of a case of specimens and text. Price, single parts 10*s.* 6*d.*; by subscription 10*s.*, with postage extra. London: English Agents, Messrs. Carl Zeiss, Limited.

THE complete work, of which we have received parts 1 to 6, will consist of ten "parts." Each part comprises (1) a case of 10 to 13 microscopical preparations mounted on 10 slides—each slide is labelled, the names being given in German, French, and English; and (2) an explanatory text of 16 to 24 pages with 20 to 30 figures in black and white after original drawings by the author.

It is claimed that the text and preparations will be useful to the biologist, zoologist, botanist, physiologist, and medical practitioner. There are, however, few medical practitioners who can afford to pay £5 for 100 microscopic preparations; and, as a matter of fact, in every well-equipped medical school where animal histology is well taught each student at the end of the course possesses a collection of microscopical specimens of normal tissues and organs, partly prepared by himself, and partly sections made for him by well-known laboratory methods. It is no uncommon thing for each student of histology in this country to make a collection of 200 specimens or even more, including not only sections prepared by the ordinary methods, but also specimens showing the terminations of nerves in the cornea, motor plates in muscle, the cochlea, and the central nervous system stained by the well-known Golgi, Cajal, and Weigert methods. We, therefore, doubt whether such sections, however well prepared and arranged, will be required by medical practitioners who were well grounded in histology during their student days. The preparations, we should add, are neatly mounted.

LIBRARY TABLE.

A Digest of the Law and Practice Relating to Local Government in England and Wales (including London). By ARTHUR D. DEAN, F.L.G.A., Solicitor of the Supreme Court, and E. J. RIMMER, of Lincoln's Inn and the Northern Circuit, Barrister-at-Law. London: Butterworth and Co. 1914. Pp. 333. Price 5s. net.—The joint compilers of this work profess to have aimed at providing a work suitable for students, officials, and councillors alike, and generally speaking they have done so. The subject, however, is a very large one, and the task of analysing and extracting the essential parts of statutes and of presenting them with clearness and accuracy is not lightly to be undertaken. We do not profess to have checked every detail in this book, but from what we have seen in portions likely to be of interest to the medical profession more meticulous care might have been exercised with advantage. We are, for example, not inclined to accept the definitions given of the coroner's powers, either where it is stated that his duty in the City in relation to fires is only "to inquire into incendiary fires," or that his principal duty is to hold an inquest over the body of "any person who has been killed, or who has died in prison, or who has died suddenly if the cause of death be unknown." The section under which coroners hold inquests would indeed be a puzzling one if it was so worded. Again, on consulting the index we are referred to p. 19 for the powers of a medical officer (presumably a medical officer of health) as to factories and workshops. At the page named, however, the regulation of hackney carriages is the subject treated. Misprints in an index are often very inconvenient, more so, of course, than unimportant literal errors in a paragraph of the text. We have not checked the "Table of Statutes," but glancing at it in connexion with subjects of medical interest we find no reference in it (or in the paragraph on medical inspection of school children) to the Local Education Authorities (Medical Treatment) Act, 1909. It is difficult to include everything in a comparatively brief synopsis, but we see no reason to omit this Act if the subject is to be dealt with, and conclude that the absence of reference to it is accidental.

Lectures on Medical Diseases for Nurses. By DAVID FORSYTH, M.D., D.Sc. Lond., F.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1914. Pp. 222. Price 3s. 6*d.* net.—This little work does not deal at all with nursing, but aims only at giving such an account of medical diseases as shall be intelligible to nurses and add to the interest of their cases. It is clearly and simply written and seems well adapted to the end in view. The author believes, we think rightly, that those nurses are keenest to learn about the nature of disease who best appreciate the limits of their own province. Some general remarks are made on treatment, prescriptions, and dietaries, and then the chief diseases of the various organs are considered in order, their causation and principal features being described and the main lines of treatment indicated. Dr. Forsyth emphasises the fact that not the disease alone but the patient has to be treated. The experienced nurse knows this well, and it is very necessary that from the beginning of their training the probationers should fully realise that such is the case. In the chapter on hysteria and psycho-neuroses the author deals adroitly with a very difficult subject. Throughout the book there is a considerable use of anatomical and pathological terms which no doubt would receive oral explanation in a lecture.

Notes on Midwifery, especially for Midwives. By C. F. LASSALLE, M.D., C.M. Edin., D.P.H. Oxon., Government Medical Officer, Port Health Officer, Port of Spain, Trinidad. Edinburgh: William Bryce. 1913. Pp. 126. Price 2*s.* 6*d.* net.—This little book is a reproduction of the lectures on midwifery given by the author to nurses at the Colonial Hospital, Trinidad. It is a series of notes, expressed in clear and simple language, of just those facts which nurses require to know, and should prove useful to the class for whom it is intended. The rules of the Midwives Board are added, and there is also a useful glossary of terms in common use.

JOURNALS AND MAGAZINES

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., ALEX. MACALISTER, ARTHUR THOMSON, ARTHUR KEITH, and ARTHUR ROBINSON. Vol. XLVIII. Third Series, Vol. IX., Part III. April, 1914. London: Charles Griffin and Company, Limited. Published quarterly at 6*s.*; annual subscription 21*s.*, post free.—This issue contains an unusual number of interesting contributions, and is especially welcome for the fact that nearly every branch of anatomical study is represented.—Professor Peter Thompson contributes to the study of embryology an interesting paper on the Development of the Lobus Quadratus of the Liver. This paper is well illustrated by reconstruction models, &c., and it confirms in many ways the findings of Cantlie upon the limits of the right and left hepatic lobes.—Professor J. T. Wilson, of Sydney, records some Observations upon Young Human Embryos, illustrated by photomicrographs of sections of an embryo of 1·64 mm. The plates which are to make this article complete are held over until next issue.—Dr. F. Wood Jones briefly describes the condition of the Lower Ends of the Wolffian Ducts in a Female Pig Embryo, the note being illustrated by a series of photomicrographs.—The study of anomalies is represented by a most useful paper by Mr. A. Ralph Thompson, upon the Congenital Abnormalities of the Upper Urinary Tract, and Some Points in the Surgical Anatomy of the Kidneys, Ureter, and Bladder. The paper is for the most part statistical, but there are several points in gross anatomy well worth further attention. Mr. Thompson sounds a warning note concerning the ready teaching and the ready acceptance of the doctrine of the free stripping of peritoneum from the anterior surface of the distended bladder. There seems to be little doubt that we are over-estimating this peritoneal stripping in our teaching, and consequently are making too light of the risks of penetrating the peritoneal cavity in suprapubic operations.—Professor A. Francis Dixon contributes a note on two cases of well-marked Suprasternal Bones. These rudiments are admirably shown in X ray pictures; their morphology is not discussed.—Mr. D. Davidson Black, of Cleveland, Ohio, describes two cases of Cardiac Malformation, and this paper is rendered more than usually interesting by some discussion of the relation of these cardiac anomalies to the cardiac functions.—Dr. Harold Rischbieth, of Adelaide, communicates a paper on an Anomaly of the Inferior Vena Cava. The anomaly, which consists of duplication of the post-renal segment, is well illustrated and fully discussed.—To physical anthropology Professor F. G. Parsons contributes an elaborate study of the Characters of the English Thigh Bone, which is a useful addition to our knowledge, since it has evolved, at any rate, a standard femur for Midland Englishmen of the Middle Ages. The results are obtained from exhaustive measurements of 300 femurs from the bone crypt of Rothwell in Northants, and the utility of such a standard for the purposes of anthropological comparisons is obvious. —An interesting study of the Inter-relationship of some Trunk Measurements and their Relation to Stature, by Dr. Rupert Downes, of Melbourne, brings out several noteworthy points, among them the fact, long insisted on by artists, that the pelvis of the male is absolutely broader than that of the female.—Mr. Bernard Coen, of Sydney, communicates a paper showing that at times diploic veins may contribute to the meningeal venous grooves upon the inner surface of the parietal bone.

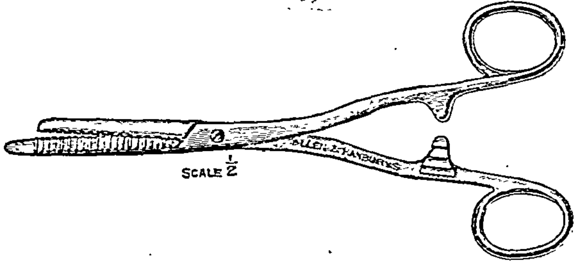
British Dental Journal.—To the issue dated May 1st of this publication Mr. F. St. J. Steadman contributes a thoughtful paper on the Treatment of Dental Caries in Children, based on his experience in the treatment of nearly 7000 children. He is a strong supporter of the free removal of all septic teeth, and ably answers the criticisms that have been brought against this method of treatment.—Dr. J. Stuart Ross gives an account of the method adopted at the Edinburgh Dental Hospital of inducing anæsthesia by means of nitrous oxide and oxygen combined with a small dose of ethyl chloride.

BIRMINGHAM GENERAL HOSPITAL.—At a meeting of the election committee on May 22nd Dr. A. Stanley Barnes, senior assistant physician, was elected honorary physician for a term of 15 years in place of Sir Robert Simon, M.D., resigned. Dr. Barnes was appointed assistant physician to the hospital in June, 1906. He is honorary curator of the pathological museum of the Birmingham University, and a Fellow of the Royal Society of Medicine. He formerly held the posts of assistant demonstrator of physiology at Mason's College, resident medical officer at the National Hospital for the Paralysed and Epileptic, Queen-square, and pathologist at the Queen's Hospital, Birmingham. He was recently elected a Fellow of the Royal College of Physicians.

New Inventions.

PERFORATING FORCEPS FOR LIGAMENTARY SUSPENSION OPERATIONS UPON THE UTERUS.

I HAVE designed a perforating forceps for those operations in which the round ligaments are employed for suspension of the retro-displaced uterus, more especially for that known as the "sling" operation. In this operation the round ligaments are drawn through an opening made in the broad ligaments and stitched to the posterior uterine wall. The instrument is in the form of a modified pressure forceps which has attached to one blade a small cutting edge that easily perforates the broad ligament, the clamp portion being used for grasping the round ligament and drawing it through the opening in the broad ligament and attaching it in position prior to stitching it to the uterine wall. In the performance of the sling operation much delay may occur through difficulty in perforating the broad ligament by blunt forceps, the tissue sometimes having to be incised with scissors, and frequently an unnecessary amount of damage may occur to the tissue. With the above instrument there is no delay and the technique is greatly improved. The instrument can also be used in Gilliam's and other intra-abdominal suspension operations upon the uterus.



The instrument has been made for me by Messrs. Allen and Hanburys, of Wigmore-street, London, W.

Glasgow. A. LOUISE MCILROY, M.D. Glasg.

THE REPORT OF THE INTER-DEPARTMENTAL COMMITTEE ON SLEEPING SICKNESS.[1]

THE work of Surgeon-General Sir David Bruce, chief of the British Sleeping Sickness Commission, led him to believe that wild animals in Nyasaland were infected with the human parasite of sleeping sickness. As a result of other researches in Central Africa he came to the conclusion that wild game constituted the main, if not the only, reservoir of the virus from which the tsetse fly derived its infectivity; and a somewhat similar opinion was expressed by Dr. Allan Kinghorn and Professor Warrington Yorke, who investigated the sleeping sickness problems in Rhodesia. One of the chief recommendations of these experts was that the effects of destruction of game in a limited area should be tried experimentally with a view to eradicate the local endemicity of the infection. These opinions were not universally accepted, and objections were at once raised against any proposal for exterminating wild game. Demands were also made for further investigation of the subject before any action was taken, and accordingly the Secretary of State for the Colonies in August of last year appointed a committee of 16 members, of whom the medical representatives were Sir John Rose Bradford, Sir William Leishman, Professor Charles J. Martin, Dr. W. A. Chapple, M.P., and Dr. A. W. G. Bagshawe, the Earl of Desart acting as chairman. The terms of reference were to report on (1) the present knowledge available as to the parts played by wild animals and tsetse flies in Africa in the maintenance and spread of trypanosome infections of man and stock; (2) whether it is feasible to carry out an experiment with regard to game destruction in a localised area; (3) whether it is advisable to attempt the extermination of wild animals locally or generally with a view of checking trypanosome diseases; and (4) whether any other measures should be taken to obtain means for controlling these infections. The report now presented is signed by all the members, but attached to it is a supplementary memorandum by Dr. Chapple and Mr. J. Duncan Millar, M.P., who, agreeing with the general conclusion that wild animals form one of the reservoirs of trypanosomes pathogenic to stock, wish to express their decided opinion that these wild animals form also one of the reservoirs of trypanosomes pathogenic to man.

---

[1] Report of the Inter-Departmental Committee on Sleeping Sickness. Presented to Both Houses of Parliament by Command of His Majesty. Printed under the authority of H.M. Stationery Office by Eyre and Spottiswoode. London. 1914. Pp. 26. Price 3*d.*

Trypanosomes and Trypanosomiasis.

The committee considered the subject under three heads: (1) the Uganda form of sleeping sickness, of which T. gambiense is the parasite, and which is spread by glossina palpalis; (2) the Nyasaland form of the disease, also occurring in Rhodesia, caused by T. rhodesiense and spread by G. morsitans; and (3) trypanosomiasis of stock transmitted by several species of glossina. Fortunately, the Uganda form of the malady is not now epidemic in that country, though from 1898 to 1906 it carried off some 200,000 of the native population. The Nyasaland variety of sleeping sickness is a more virulent disease, but at the present time it does not appear to be extending. As regards the trypanosomiasis of stock, it is found practically wherever tsetse flies of any species exist. Some experts look upon T. rhodesiense and T. brucei, the parasite of nagana in animals, as being identical, though other authorities deny this identity. It appears that there may be mechanical transmission of these trypanosomes by other sorts of flies, but the tsetse fly plays the preponderating part in the maintenance of both human and animal trypanosomiasis in Africa; these flies are not merely passive carriers of an existing virus, but are living "culture-chambers" in which the virus multiplies indefinitely. The habits of Glossina palpalis are fairly well known and its haunts recognised, but less has been ascertained respecting G. morsitans, which, moreover, has a much wider distribution.

The Reservoirs of the Virus.

The tsetse flies live on the blood of vertebrates, and G. palpalis especially attacks man with avidity. In nature this species, partly from its association with water, has special opportunities for feeding on aquatic animals, such as hippopotamus or crocodile. In this connexion it may be remembered[2] that the late Professor Koch, while investigating sleeping sickness around the shores of the Victoria Nyanza, was led to suspect the crocodile for a time of being a reservoir of the virus owing to his finding crocodile's blood in the stomach and intestines of almost every tsetse fly he examined. Dr. G. Bouffert, the French expert, mentions that along the Bani river, a tributary of the Niger, there is a region long abandoned by the natives which continues to be a focus of sleeping sickness, this being due in his opinion to the crocodile or the hippopotamus acting as a reservoir of the T. gambiense infection. The scientific case for regarding wild animals as the reservoirs of the virus of trypanosomiasis in certain parts of Africa rests mainly on the observations of Sir David Bruce, Dr. Kinghorn, and Professor Yorke.

These observers found trypanosomes resembling T. rhodesiense in the blood of wild animals, and especially in various kinds of antelope. Many foreign investigators do not believe, however, that wild animals are reservoirs of T. rhodesiense, and among these is Dr. Taute, the German expert, who regards this trypanosome as distinct from T. brucei, and who made an unsuccessful attempt to inoculate himself with the latter organism. It is therefore not yet settled whether the wild animals which are known to be a reservoir of the disease affecting stock are in reality a danger to man in Nyasaland and Rhodesia. But while the exact relationship between human and animal trypanosomiasis cannot be said to be fully established, the committee think that the evidence indicates that game may also serve as a reservoir of the human form of the disease.

The Suggested Experiment of Game Destruction in a Localised Area.

As knowledge of this disease, its cause and its remedies, is still in the making, any hasty and imperfectly considered action of a drastic kind, such as general extermination of game, is in the opinion of the committee not justified so far by the evidence brought forward; but they recommend that until direct means of checking the fly have been discovered, the food-supply of glossinæ and the chances of infection should be lessened in the vicinity of centres of population and trade routes by the removal of wild animals; and for that purpose freedom should be granted to settlers and natives to hunt and destroy the animals within the prescribed areas, subject to certain conditions. The proposed experiment of removal of wild animals from a selected area may be instrumental in producing valuable results both as regards our knowledge of the habits of the tsetse fly, and as to the extent to which the infectivity of the fly, and subsequently the infection of man or stock, is derived from the wild animals. The committee think that there are sufficient grounds to justify an expectation of useful results, and they recommend that if a suitable locality can be found where an experiment can be carried out at a reasonable cost it should be undertaken.

Other Measures Suggested.

Meanwhile other measures should not be delayed pending the result of the above-mentioned experiment, which would necessarily take time, probably two or three years, before definite results could be obtained. These other measures include clearing of growth, especially in the neighbourhood of water and other places where the fly seeks shelter. There is a general consensus of opinion that if land in a fly country is cleared of bush it will cease to be the permanent habitation of glossinæ, though the fly may occasionally follow men or animals into cleared areas. The committee regard the question of the possibility of removing the fly from the neighbourhood of villages, settlements, or roads, by the clearing of bush, as being one of high importance. They strongly recommend that wherever practicable clearing should be undertaken, as it would tend to check the spread of the disease and render life in settlements and travel by road safe for man and stock. The extensive clearing of areas near villages would bring some material return by an increase of tillage land or additional pastures where cattle could be safely kept. Whether for tillage or pasture the cleared land would need to be enclosed by substantial fencing to prevent the intrusion of wild animals. The committee have no doubt that the settlement and cultivation of land on a considerable scale will result in the disappearance of the tsetse fly. If this fly could be eliminated or removed from contact with human settlements, sleeping sickness would practically disappear. For this reason great importance is also attached to a proper and sufficient equipment of entomological research into the bionomics of the incriminated tsetse flies, this form of research not having been sufficiently pursued in the past. Different views were taken by various witnesses as to the prospect of dealing with the fly; but some believed, and in this the committee concur, that in this form of research there is a large element of chance; that accident may at any time lay bare a secret which may lead to the solution of the problem, and that the multiplication of workers is the multiplication of these chances. It is also urged that medical research as to the treatment of trypanosomiasis and the production of immunity should be continued.

The Supplementary Memorandum.

Dr. Chapple and Mr. Duncan Millar support the view that wild animals form one of the reservoirs of trypanosomes pathogenic to man, and appear to be of opinion that the preventive aspect of the problem has not received sufficient prominence in the general report. Having regard to the havoc wrought amongst domestic stock by trypanosomiasis and to the obstacle thereby placed in the way of settlement and of the opening up of trades routes in all regions where game and fly are found, they think that on this score alone there is urgent need for immediate preventive operations. The presence of game and fly in all areas inhabited by whites and natives carries with it the dangers of infection of man. They therefore advise that in addition to the clearing measures urged in the main report further means should be taken for the destruction or driving off of wild animals in the vicinity of settlements within prescribed limits; that complete freedom should be afforded to all whites and natives to hunt, drive back, or destroy game; and that the operation of the game laws should be altogether suspended within such limits. The opinion is also expressed that no game reserves should be formed in fly-infested areas where there is any native population or in their immediate vicinity. While recommending these measures, they are opposed to any scheme for the general destruction of game outside prescribed areas.

THE LANCET.

LONDON: SATURDAY, MAY 30, 1914.

Cancer Houses.

IN an address delivered by Sir THOMAS OLIVER before the Insurance Institute at Newcastle-on-Tyne, and printed recently in THE LANCET, certain passages occurred dealing with the subject of alleged "cancer houses" which caught the lay imagination at once. Considerable prominence was given to Sir THOMAS OLIVER'S observations by the *Times* in an article which quoted extracts from our columns, and was interpreted, we believe, as an invitation for correspondence on a subject which has always interested deeply the public, especially that section of it which delights to be made to shiver. It may be well to preface these remarks, therefore, by saying that recent scientific inquiry has made available no evidence approaching to satisfactory proof as to the existence of this alleged phase of a cancer infectivity. It is clearly a phase proof of the existence of which must be accompanied or preceded by evidence of a more general dissemination of the disease by infection. At present the position would seem to be summarised by two sentences in Sir THOMAS OLIVER'S own address: "The subject of cancer houses has periodically attracted attention. ...... Many medical men are of opinion that cancer germs lurk in houses"; though here we should like to point out that though many individual medical men may have expressed some belief of the sort, the proportion of medical men holding the view is small. The opinions of medical men upon such a subject are entitled to all respect, so long as the data upon which they are founded can be shown either to be facts observed by themselves or statements so thoroughly inquired into, if they are in the nature of hearsay, that they seem to be beyond reasonable question. Such data can be compared with others from equally trustworthy sources. The whole subject of cancer, however, owing to the position which it occupies in the public mind, is so prolific in rumours and stories founded upon inaccurate lay observation that inquiries which seem sufficient to one inexperienced in the necessary precautions of research may only serve to mislead, and the disease is in itself one in which the room for error, even when the observer is a medical man of some experience, has to be taken into account. There has been a recent illustration of lay credulity in the case of the infamous quack, DELVINE, who has been sent to prison upon his own plea of guilty for obtaining money by false pretences from persons to whom he used to display fragments of offal purchased from butchers as cancerous growths removed from their bodies by his agency. DELVINE may have roused the indignation of some of his victims throughout the country, who felt that they had been robbed, but his counsel before he was sentenced stated that he had eight people present in court who would have been ready to testify on oath that the prisoner had cured them of cancer if he had chosen to face the evidence against him and submit his case to a jury. This example of willingness to be duped may be extraordinary, but between it and the statements of witnesses which will stand close scientific investigation there are many degrees of self-deception, of prejudice, and of lack of accuracy, not confined to the classes from which DELVINE'S victims were drawn, and medical men, like others, may be deceived in making inquiries of a kind outside the scope of their daily routine.

In view of the prominence that is now being given to supposed retention by certain dwellings of a special cancer virus, we would ask our readers to consider the whole matter from the point of view of evidence. Those who allege that "cancer houses" exist have the onus laid upon them of proving that certain successive cases of cancer proved to have occurred in certain houses have been due to the persons affected becoming tenants of those houses and to no other cause. The facts established must lead us to the conclusion that infection preserved in the houses has been responsible and our reason must be compelled to arrive at such a verdict. The facts must point directly to the responsibility of the building in which the patients lived, and not merely be consistent with an infected building. A man is not tried and sent to prison upon the proof of facts which are merely consistent with his guilt, except upon the stage—at least, when such a thing does occur in real life a haunting sense of possible judicial error remains. Conviction before the tribunal of public opinion is liable to be obtained by looser and easier methods than before a court jealous to observe and trained to apply the laws of scientific evidence. The difficulty is to obtain a series of houses in which the requisite series of cases of cancer can be found to have occurred, and to eliminate from those cases the possibility of their having been due as much to hereditary tendencies, which in the sifting of evidence cannot be ruled out, or to industries causing a predisposition to cancer, or to other influences. That successive cases of cancer should appear in a single house or in a group of houses is not in itself surprising, for it is not a rare disease, population has increased, and there are crowded areas and houses in which many persons will be found who are of the age with which the development of cancer is associated, so that the element of coincidence is not easy to eliminate. Unfortunately, the romantic mind never will try to eliminate it; the romantic mind revels in the trouble caused by coincidence.

Meanwhile, experiment tends to discredit rather than to confirm the existence of cancer houses, just as the sifting of the evidence connected with individual buildings brings about in many instances a similar result. In the article in the *Times*, to which we have already referred, there was a description of results said to have been observed with regard to mice confined in a cage the inmates of which were stated to have developed cancer with a frequency pointing to infection. We believe the observation has been recorded on several separate occasions. If this had actually occurred owing to the infection of the cage by diseased mice, further experiments should long ago have proved up to the hilt the existence of "cancer houses" so far as mice are concerned. But neither the experiments made under the auspices of the Cancer Research Fund, nor those of Professor EHRLICH, have shown anything of the kind. Mice have been so bred from cancerous parents that a strain has been produced in which cancer is more frequent than in families of mice in which no attempt has been made to concentrate the hereditary factor. This confirms the view that a hereditary factor may coöperate in the causation of cancer, and may be responsible for the ill-fame of some alleged cancer houses. Mice, however, have been confined in cages in which they had every opportunity to develop cancer by infection from their companions or from their cages without any apparent increase in their liability to the disease. The result, in short, has been the same as if the cages had been beyond suspicion of infection, and experiments deliberately planned and carried out must be regarded as conclusive in comparison with isolated phenomena into which an element due to chance or some unknown factor may have entered. In the present condition of things it is not likely that unanimity will be obtained or that all will accept the views of those responsible for the investigations of the Imperial Cancer Research Fund, who, however, are known not to leave any clue uninvestigated which examination may show to be worth following up. Unanimity, even upon such a question as that of the alleged general increase of cancer, is not at present attainable. Scientific investigation and proof should always precede statements which are liable to alarm the public unnecessarily. Among these we would include allegations of the existence of "cancer houses." They have not yet been proved to exist, and there is no such weight even of opinion in favour of their existence as would warrant alarming the large number of people who now live securely in houses in which deaths from cancer have taken place.

◆

Subarachnoid Medication for Cerebro-spinal Syphilis.

ONLY a few years have passed since first it was proposed to inject drugs into the subarachnoid space. It was in 1891 that QUINCKE introduced lumbar puncture, and this was the starting point of all the diagnostic and therapeutic work which has been carried out on the cerebro-spinal fluid. For diagnostic purposes lumbar puncture has proved of great value, but therapeutically the removal of a certain amount of cerebro-spinal fluid has been shown to do little good, and indeed when performed for decompression in cases of cerebral tumour the procedure has not rarely been followed by sudden death. Again, the channel of the cerebro-spinal fluid is widely used for the production of anæsthesia of the lower half of the body. This was first employed by CORNING in 1885 and later by BIER, and the practice has been found to possess a distinct though somewhat limited field of usefulness. But the more ambitious attempt of JONNESCO, of Bucharest, to employ the same method for anæsthesia of nearly the whole body by injecting the anæsthetic substance high in the cervical region has met with little favour, at least in this country. Subthecal medication has also been used in the treatment of tetanus, and a certain number of recoveries have followed this procedure; but it is somewhat doubtful whether any of the recoveries were to be attributed to the use of the antitoxin, for in any group of cases of tetanus a certain number will recover, and it did not appear that the percentage of recoveries was greater with this method than with others.

The latest example of the employment of the subarachnoid space for the administration of a remedy has been in the treatment of cerebro-spinal syphilis. It had long been recognised that locomotor ataxia and general paralysis of the insane were somehow connected with syphilis, and although some observers were of opinion that they were the direct result of the disease, it has only been since the spirochæte has been demonstrated in the brain and spinal cord that the correctness of this view could be regarded as proved. The fact that antisyphilitic remedies administered in the ordinary ways had little or no effect on tabes and general paralysis naturally lent much support to those who maintained that these diseases were not syphilitic in nature. Yet the spirochæte has now been seen in the brain and spinal cord; there can therefore be but one explanation of the failure of remedial agents, and that is that the remedy does not pass through into the true substance of the central nervous system. This also holds good in the case of the recent additions to our antisyphilitic armamentarium, salvarsan and neosalvarsan, for at no time after an injection, whether intramuscular or intravenous, can any arsenic be found in the cerebro-spinal fluid. In this connexion we may notice a very important distinction which has been drawn by MCINTOSH between two classes of syphilitic lesions of the brain and spinal cord; he divides them into the "interstitial," in which the meninges, the blood-vessels, and the neuroglia are affected primarily, the neurons only being damaged mechanically, and the "parenchymatous," in which the neurons themselves are first attacked. The distinction is important, for while the interstitial lesions may be benefited by remedies introduced into the blood stream, the parenchymatous are not amenable, since the neurons are surrounded by lymph-spaces which are in connexion with the cerebro-spinal fluid, and this, as we have remarked, does not contain chemical substances introduced into the blood stream. The conclusion, therefore, seems to be obvious that if we desire to influence the spirochætes in the parenchyma of the central nervous system we must introduce the remedy directly into the cerebro-spinal fluid; and in the present issue of The Lancet we publish three papers of no little importance which deal with work in this direction.

Nierenstein, it will be remembered, succeeded in showing that arsenical compounds had no effect on trypanosomes *in vitro*, although the organisms died if some protein were added. It follows from this that the protein forms a compound with the arsenic, and that this compound acts upon the trypanosomes, killing them; and the same is true also of salvarsan and the spirochæte of syphilis. It appears, therefore, to be necessary to combine the salvarsan with a protein before injecting it into the cerebro-spinal fluid, and Dr. Gordon W. Spencer's paper deals with cases in which salvarsanised serum has been injected into the subarachnoid space. The salvarsan is first injected intravenously into the patient, and after an interval some blood is withdrawn; the serum is then separated and is injected through a needle by which an equal quantity of cerebro-spinal fluid has just previously been withdrawn by lumbar puncture. Dr. Spencer has worked out the details of the technique, but necessarily some of the points may be modified as time goes on, such as the period after the intravenous injection when the blood is best withdrawn and the most suitable quantity to employ. These, however, are small points, and the paper is of value, for it contains particulars of 12 cases in which this mode of treatment has been made use of. Seven of the patients suffered from tabes, and five from sclerosis and interstitial cord lesions. The results varied, but in the majority of the cases there was more or less improvement, and in no case did any perceptible harm follow the injection.

Mr. C. A. Ballance and Dr. Harry Campbell deal in their instructive papers with the treatment of intracerebral parenchymatous syphilis. The foundation of the work which they have done is the fact that it is apparently impossible by introducing a drug into the spinal portion of the subarachnoid space to influence the brain above the tentorium cerebelli, for the cerebro-spinal fluid below this does not pass upwards, the stream being in the opposite direction. Mr. Ballance has introduced the remedial agent directly into the lateral ventricle, so that the drug is carried with the stream over the surface of the brain and into all its lymph spaces. As to the results, it may be said that they were encouraging, but it is too early to form any definite conclusions. The authors quote previous attempts which have been made in the same direction, yet their own papers mark a very distinct advance in the therapy of some forms of cerebral syphilis. We have now a means of attacking the disease even in fastnesses where it has hitherto been safe from our efforts at destruction. Doubtless time will show the modifications which the method may need, and will also tell how far success may be counted upon; but enough has already been done to justify us in thinking that a real advance in the treatment of syphilis has been recorded.

Annotations.

"Ne quid nimis."

THE TREATMENT OF INFANTILE PARALYSIS.

The recent advances in our knowledge of the nature of the infecting agent in infantile paralysis have perhaps tended to divert attention from the almost equally important steps which have been taken to improve the treatment of this affection, which we now know to be, after tuberculosis, the most important cause of crippling deformities. Mr. Robert Jones's oration before the Medical Society of London (which will be found at p. 1515 of our present issue) comes not only, as he himself states, from one whose "life has been devoted to the more practical and clinical aspect of surgery," but also from one whose teaching of *simple principles* has done much to advance the treatment of infantile paralysis. In the past the functions of the neurologist and of the orthopædic surgeon have been too far divorced from each other. The principle of the treatment of paralysed muscles by the relaxation of tension, one of the legacies to Mr. Jones from his predecessor, Mr. H. O. Thomas, has brought the two together. Rest in the early stages of the disease no longer means simple rest in bed, but fixation upon a splint in a carefully thought out position, so that the limb may be completely rested, the paralysed muscles relieved from tension, and contractures prevented. When once this principle has secured general acceptance and is universally applied, half the work of the orthopædic surgeon, that involving the correction of deformity, will have gone. It is very doubtful whether it is possible at the present time to differentiate in the early stages of infantile paralysis between those muscles which are irreparably damaged and those which will probably recover their power. The electrical reactions give no certain guide; muscles which exhibit the reaction of degeneration or which even fail to react at all to electric stimulation have been seen to recover. It is as well that, therefore, all paralysed muscles should be treated as if they might regain their power. Mr. Jones would not abandon hope unless there is no sign of return of muscular action after 12 months' "appropriate treatment." By this he means treatment including the support of the affected muscles by a splint, so that they are never placed upon the stretch. To this he gives the first place in treatment; all other methods are subsidiary, and must be carried out in such a way as not to interfere with efficient splinting. Electrical treatment in particular is now given its proper value; its effect is nutritional only. Massage serves the same purpose, perhaps more effectually, for it can be applied gently and with accuracy to definite muscles or muscle groups. Exercises are important in proportion as the muscles are able to carry them out. Attempts to obtain full active movements of the joints whilst the muscles are still too weak to act against the resistance of weight are, however, worse than useless; they not only fail to exercise the muscles, but by stretching them delay recovery. Mr. Jones has rightly achieved a reputation as a pioneer of operative methods in the treatment of infantile paralysis, but it may be predicted that in the future he will be remembered rather for his insistence upon this principle of rest and relaxation of paralysed muscles than for the work he has done to improve the methods and results of such operations as arthrodesis and tendon transplantation. These operations have their use, the former in flail limbs, the latter in paralyses of limited distribution, but they must be reserved until after conservative treatment has been given its trial. There can be no doubt that they have been too widely used. Tendon transplantation is worthless unless the tendon can be securely fixed with a suitable degree of tension, made to work in a good line, and given a reasonable chance of carrying out a useful function in its new position. Arthrodesis and similar operations have an even more limited field. It is interesting to find that Mr. Jones now practically confines this operation to the ankle and shoulder. The subject of nerve transplantation for paralysis is a fascinating one. Up to the present little success has been obtained by workers in this field, although much has been added to our knowledge. In particular Stöffel's investigations into the minute anatomy of nerve trunks, where he is able to recognise the bundles which supply individual muscles, seem to lead on to more accurate methods of nerve crossing. Yet when we remember the comparative uncertainty of suture of a healthy nerve immediately after section, and the fact that in a paralysed limb we are faced with the additional feature of prolonged disuse, the prospects of obtaining a sufficient regeneration of a transplanted nerve to enable the paralysed muscle to become functionally active must be remote. There is still another difficulty, the number of functionally active neurons in the paralysed limb is small; in attempting to transfer some of these to the paralysed muscle we must abstract them from a functionally active muscle. So that the operation is at best a mutilating one, and until we can be sure that there is a reasonable prospect of regeneration of the nerve and of a restoration of function in the muscle it can scarcely be considered a surgical procedure. Still further experiments, particularly upon muscles which have been long disused, are required.

THE HISTORICAL MEDICAL MUSEUM.

A FEW weeks ago we announced that the Historical Medical Museum founded last year by Mr. H. S. Wellcome in connexion with the International Medical Congress would shortly be reopened at 54A, Wigmore-street, London, W., as a permanent institution. During the past six or seven months considerable additions have been made to the collection, and the exhibits have been rearranged and classified under the supervision of the curator, Mr. C. J. S. Thompson. Among the recently acquired objects of interest are a case of chemical reagents and apparatus used by Lister in his early experimental days, and the 12 interesting oil paintings of anatomical subjects attributed to Jacques Gautier D'Agoty, which were described in THE LANCET of Feb. 21st last, p. 557. These latter were purchased only a few weeks ago for the museum; they have been carefully relined and restored, and are well worth a visit. The museum, which was reopened informally on Thursday of this week, has a definite educational value. That it is an object of abiding pleasure and instruction to all students of the historical and archæological aspects of the art of medicine scarcely needs further emphasis in these columns. It will be open daily from 10 A.M. to 6 P.M., closing at 1 P.M. on Saturdays. Members of the medical and kindred professions will be admitted on presenting their visiting cards. Tickets of admission may also be obtained by others interested in the subject on application to the curator together with an introduction from a registered medical practitioner. Ladies will be admitted only if accompanied by a medical practitioner.

THE ESSENTIAL FEATURES OF ACIDOSIS.

SOME new researches into acidosis, together with a review of the whole subject, are contributed to the *Johns Hopkins Hospital Bulletin* for May by Dr. A. W. Sellards. His conclusions are confidently expressed as follows. The essential feature in acidosis consists in a general impoverishment of the body in bases or in substances which readily give rise to bases—e.g., sodium carbonate. This may occur through the loss of bases as such (relative acidosis) or by the neutralisation by acids (absolute acidosis). In either case the end result is the same, and the distinction between relative and absolute acidosis is misleading. In every acidosis there is an increase in the tolerance of the body to fixed bases, a diminution in the titratable alkalinity of the blood serum, and a diminution in the carbon dioxide of the blood. The excretion of ammonia either in its relative or absolute amounts does not afford a definite basis for the detection of acidosis; indeed, ammonia excretion may be normal in acidosis, especially in diabetic cases. In cases of nephritis with diminished ammonia in the urine it is probable that there is no increase in the quantity of ammonia in the blood. This view, we may note, is contrary to the teaching of many authorities in this country. An acidosis of high degree occurs in certain nephropathies; it reaches a maximum in the uræmia of acute and chronic diffuse nephritis. It is not a terminal event, for it is frequently present in a high degree months before uræmia develops. In this type of acidosis there is a normal excretion of ammonia and an absence of disturbance of carbohydrate or fat metabolism and an absence of the salts of any abnormal organic acids. The changes in the titratable alkalinity of the blood which can be detected by phenolphthalein afford a ready means for the prompt diagnosis of acidosis, and the method is particularly applicable in renal disease. In this condition it furnishes a definite indication of the amount of bicarbonate that will be required for the relief of the acidosis. The determination of the tolerance of the body to sodium bicarbonate also affords a delicate method of general application for the detection of acidosis. Even when massive doses of this salt have been given there is no excretion of it in the fæces. Some of the toxic symptoms of uræmia are due, not to the presence of a toxin, but to the absence of a normal constituent of the blood—namely, carbonates. Therefore, to bleed in order to remove toxins from the circulation causes a still further diminution in a substance of which the blood is already seriously depleted. This disadvantage can be obviated by injecting bicarbonate solution at the time of bleeding. In the selection of carbonates for therapy the bicarbonate meets the essential requirements; the use of sodium carbonate is unnecessary and inadvisable.

THE HARDSHIPS OF HARD WATER.

THERE can be little doubt that a soft water drinking supply, apart from the question of whether hard water is injurious to health, is invariably appreciated, and yet nowhere is really soft water supplied in the immediate metropolitan area. The hardness of the metropolitan water-supply varies, of course, according to its source. The water drawn from the rivers is hard, but nothing like so hard as the water drawn from the chalk wells in Kent. It is true that for organic purity the water supplied from the chalk wells surpasses that drawn from the rivers, although now that storage and filtration are the rule the latter water maintains a remarkable and desirable standard of purity. The public, however, who enjoy the privilege of a water-supply showing the very high degree of purity of that drawn from the chalk wells of Kent labour under the great disadvantage which it presents through being extremely hard. Their share of the water rates is increased by the expense of having to employ the plumber at short intervals to remove the calcareous deposit which rapidly accumulates in the pipes and boilers of the hot water service. Pipes of two-inch diameter quickly have their calibre reduced to half an inch or less, and old pipes are frequently taken out with a free way not much larger than would admit a penholder. The economic loss is of course considerable, and this "furring" is attended with some danger owing to the pipes being liable to be choked up altogether. It does not seem reasonable that this real trouble and nuisance should be inflicted upon one section of the community which is part of the same administrative system supplying comparatively soft water to other districts. Further, the comparatively soft water-supplies drawn from the river sources have to go through expensive processes of storage and filtration before they are sent to the consumer. The hard chalk supplies of the Kent wells go through no such process, and therefore are most probably delivered at a much lower distributing cost. Surely, therefore, it is not asking too much that these excessively hard water-supplies should be softened by well-known processes before they are pumped through the main services, thus removing a real reproach to the water as it is at present supplied. It is fortunate for the people of Southend in Essex that there are in their case natural processes at work which automatically soften the water before it reaches the pumps. Here apparently, as shown in an article which we publish this week, the initial subterranean chalk water contains some infiltrated sea water, but in its passage through Thanet sand the calcium and magnesium salts are replaced by sodium salts, and so the Southend water-supply is not only very soft and free from chalk, but contains an appreciable amount of alkaline salts. This state of things will be envied by the inhabitants of Kent, who find their own water-supply a daily inconvenience and nuisance on account of its excessive hardness. Finally, it should be remembered that whether it is a natural or artificial softening process the resulting water attains a higher degree of purity than ever. We think that a strong appeal might be made to relieve the districts served with excessively hard water from the hardships which its use entails in many directions.

THE APPLICATION OF ABDERHALDEN'S REACTION TO THE STUDY OF NERVOUS AND MENTAL DISEASE.[1]

IT is well known that before any alimentary substance can reach the cells of the organism it must pass the intestinal mucosa, where it undergoes considerable modification. Proteins, for instance, are decomposed by intestinal ferments, and subsequently undergo a synthesis into proteins differing from those in the food substances as introduced, but analogous to those circulating in the blood plasma. In this way the tissues never come in contact with substances foreign to the particular animal species concerned. The tissue cells of the body are supplied with ferments rendering them capable of assimilating the albuminoids, carbohydrates, and other foodstuffs contained in the plasma. The question then arises whether the plasma might not acquire fresh properties if foreign substances are introduced into the body avoiding the alimentary canal. Abderhalden has shown that it is so, and that the organism can produce new ferments in response, for instance, to the injection of certain sugars, such as saccharose, lactose, or of such substances as the nucleins and nucleic acids. The exact origin of these defence-ferments ("abwehrfermente") is still obscure. From this discovery Abderhalden was led to suppose that in pregnancy new ferments might be discovered existing in the blood as a defence-reaction to the albumin of the placenta, and it now seems thoroughly established that this is the case, and that from about the eighth day after fecundation to some 14 or 20 days after the expulsion of the placenta these specific ferments are present and their presence can be demonstrated as a specific test for pregnancy. Whether the ferments of Abderhalden are or are not identical with, or analogous to, antibodies is a matter for further investigation. But the applicability of the method of Abderhalden to other conditions may soon become of paramount importance. Already considerable progress has been made in connexion with its application to the problems of nervous and mental disease by German and French investigators. All agree that normal serums never contain defence-ferments directed against the albumin of the brain or any other organ. Now in dementia præcox it has already been shown by a number of observers that the blood contains ferments to counteract the albumin of the sexual glands; the serum of female cases of the disease acts on proteins of ovarian origin and is inert in reference to proteins from the testis, while the converse is the case in male patients. Further, similar reactions have been found in dementia præcox in regard both to the thyroid and the cerebral cortex, while analogous investigations have been made in such diseases as epilepsy, general paralysis, exophthalmic goitre, paralysis agitans, and in organic and functional psychoses, and interesting results are being obtained. It is true, of course, that we are merely at the beginning of investigation along these new lines, but the data already recorded suggest that from this new sero-reaction appreciable benefits will accrue as far as the etiology, diagnosis, and treatment of certain nervous and mental diseases are concerned.

THE INVESTIGATION OF OZÆNA.

THE International Collective Investigation of Ozæna, which originated at the Rhino-Laryngological Congress in Berlin in 1911, has suffered by the death of Professor Grabower early this year a serious loss. But the investigation is being steadily pursued, and a fresh impetus has been given to it by the unearthing of the fifteen years old researches of Dr. Fernando Perez, of Buenos Aires. This writer described in the *Annales de l'Institut Pasteur* in December, 1899, a small polymorphous Gram-negative immobile rod as the exciting cause of ozæna; he named it the coccobacillus fœtidus ozænæ, but his communications received no attention. In the *Journal of Laryngology, Rhinology, and Otology* Dr. A. Brown Kelly describes the long-deferred recognition of these researches and the further problems which they suggest for consideration. The Berlin committee, it appears, last year invited Dr. Perez to submit his views to the Institute of Sero-Therapeutics in the University of Vienna, where they were completely confirmed. The organism which Dr. Perez believes to be the specific cause of ozæna is only one out of 11 which he has found in the nose in cases of that disease: the others are all well-known members of the nasal flora. It stains with aniline dyes, but is Gram-negative. On the usual media it grows well at body temperature; it does not liquefy gelatin, never curdles milk, and produces ammoniacal fermentation of urine. All cultures of this coccobacillus give off a characteristic odour exactly similar to that of ozæna itself. Inoculation of $\frac{1}{4}$ c.c. of a bouillon culture into the circulation of a rabbit leads to death in 24 hours; the outstanding post-mortem change is inflammation of the nasal mucous membranes, whence the organism can be recovered. If the animal recovers from inoculation it suffers from a chronic nasal discharge, in which the organism is again found; in time atrophy of the anterior turbinal develops. Dogs also can be infected with the cocco-bacillus, and indeed it occurs normally in the dog's nose, increasing in those which have distemper. It is not found in the nasal cavities of other domestic animals; the dog alone, and particularly the diseased dog, can transmit it. This discovery raises very important questions as to the method of infection. Dr. Perez shows that in many cases it exists in more than one member of the same family, and is therefore probably contagious; but when a solitary case occurs the possibility of canine infection has to be thought of. These results have been confirmed and extended by Hofer[1] and Koller,[2] who have used vaccines of the organism therapeutically with marked success. Sufficient time has not yet elapsed to show whether the improvement amounts to permanent cure, but optimistic accounts are given. The collective investigation is so much impressed by these results that further researches are being carried on under its auspices in Berlin, Vienna, Budapest, Prague, Königsberg, Posen, Christiania, Turin, and Glasgow. At the Hamburg Congress to be held in 1915 a review will be presented of all the reports received from the different countries in which the investigations have been carried on; this and everything bearing on the subject will be published in a special volume. Intimation of papers, mentioning subject and length, are asked for by the Berlin committee by July 1st next; and papers themselves (as far as Great Britain and the Colonies are concerned) should be in the hands of Dr. Brown Kelly, of Glasgow, not later than Dec. 1st next.

AN EARLY MEDICAL REVIEW.

IN an annotation on "One of our Predecessors," published on Nov. 3rd, 1906, we drew attention to the fact that as long ago as June 17th, 1684, a single number of what is perhaps the earliest instance of an English medical periodical was issued under the title of "Medicina Curiosa, or a Variety of New Communications in Physick." Subsequent research has failed to discover any purely medical English predecessor to this journal, for the "Zodiacus Medico-Gallicus"[1] was a Genevese periodical. But both the "Zodiacus" and the "Medicina" were preceded by publications, not specifically medical, which still dealt largely with medicine. Thus perhaps the earliest scientific review to make its appearance in England was the "Weekly Memorials for the Ingenious: or An Account of Books, with other Curious Novelties." It appeared as early as Jan. 23rd, 1681, and was issued every "Munday" by Faithorne and Kersey at the Rose in St. Paul's Churchyard, being reprinted as a volume in 1683 with a dedication to the Hon. Robert Boyle, the popular man of science of the period. Unlike modern critical journals it was uniformly complimentary in tone, and aimed only at giving a clear account of books of interest to the learned or the curious. Doubtless, its inspiration was drawn from the "Zodiacus Medico-Gallicus," published by Nicolas de Blegny, of which it gave some account in its fourth number, Feb. 6th, 1681. It is only in a sense correct, however, to regard the "Zodiacus" as the pioneer of all medical journals, for its publication dates only from 1679, and it seems to have been suggested to the ingenious de Blegny by our own "Philosophical Transactions," first appearing in 1665, and by the "Journal des Scavans" of the same date, as well as by the "Miscellanea Medico-Physica" (1670) and "Acta Eruditorum" (1682), both of Leipsic, and the "Acta Medica et Philosophica" of Copenhagen (1671). All these early learned periodicals reviewed medicine, but the "Weekly Memorials" are almost exclusively devoted to it, and supply much information, which, though quaint, is manifestly put forward in the best interests of science. Thus of Peyer we read that "the anatomical knowledge of the stomach and guts, gives so great an insight into the natures and operations of aliments, medicines, and several diseases, that this curious and industrious anatomist has been encouraged thereby to bestow much time, and pains in the search and discovery of those parts," but in view of the previous labours of Willis and of Wepfer, he has specialised in the "glandules." Two reviews are devoted to a description of the patches named after him. In a review of the Comparative Anatomy of Gerard Blasius the great importance of the dissection of animals is insisted upon as leading to a knowledge of the human body. Finally, immense calculi are described, and marvellous stories of drugs and their action, accidents, cures, and so forth, are recounted for the delectation of a credulous if intelligent generation.

A NEW PREPARALYTIC SYMPTOM IN ACUTE POLIOMYELITIS.

WITH the fuller knowledge that has been gained of acute poliomyelitis, and with the possibility now before us of inoculating protective cultures for this condition, any sign which is clinically recognisable as premonitory has a warning value of especial importance; and more especially is this the case since it has not been proved up to now that such an inoculation, when once the disease is definitely present, has any effect in either limiting the extent of the paralysis or checking the subjective associated symptoms. Only in the preparalytic stage can benefit from such inoculations be anticipated. Dr. John Colliver, during a recent epidemic of infantile paralysis in Los Angeles, in which a hundred cases occurred, states in the *Journal of the American Medical Association* (1913, vol. lx., p. 813) that in 16 cases he was able to observe certain signs which were definitely premonitory of severer attacks. Such signs were in the nature of a tremor or convulsion of certain groups of muscles; the movements last from a few seconds to less than a minute; usually they affect a part or the whole of one or more limbs. At the commencement such movements are easily missed, but later they last longer and occur at shorter intervals. The movement is associated with a cry which resembles that of the hydrocephalic. Occasionally lapses of consciousness occur which may not be associated with movements. Further observations of this nature, if confirmatory, may enable an early diagnosis to be made, and with the improved methods of treatment, especially of a prophylactic character, a notable lessening of poliomyelitis may be hoped for.

THE PHARMACEUTICAL SOCIETY.

THE Pharmaceutical Society at the end of 73 years of existence finds itself in a more flourishing condition than it has ever been. The report of the council which was presented at the annual meeting last week shows that during the year considerable progress was made in all departments and that a numerical strength of about 8000 has been reached. This on a register of 16,000 pharmacists may be regarded as satisfactory, since it is probable that between 5000 and 6000 of the qualified chemists who are not members of the society are acting in the capacity of assistants, or at any rate are not in business on their own account. To a large extent the increased activity in pharmaceutical circles is due directly or indirectly to the National Insurance Act, which has impressed upon pharmacists the need for greater vigilance and a lively interest in the developments of national health insurance. In nearly every part of the country local organisation has been raised to a high pitch of efficiency, and about 60 new local associations have been formed. A few years' experience of the value of direct representation of pharmacy in the House of Commons has convinced the council of the need for ensuring that such representation should be as far as possible permanent, and accordingly a Pharmaceutical Parliamentary Fund was established during the year to be utilised for the purpose of maintaining the present representation, and if possible increasing it. In the domain of education the only noteworthy development of recent date was the dropping of Latin from the compulsory part of the preliminary examination. This step was taken after mature consideration and no doubt regretfully, but the report shows that the decision was justified, for almost immediately the change had been made there was a large increase in the number of persons applying for registration as students. When Latin was a compulsory requirement at the first examination it was found that owing to the decrease in the number of secondary schools in which Latin was taught a large number of eligible persons who had not contemplated entering pharmacy while at school had not taken Latin, with the result that possible recruits to the ranks of pharmacy went into other callings. A knowledge of Latin is still required for the qualifying examination so far as it relates to the translation and interpretation of prescriptions. On the whole the report seems to convey the impression that the prospects of pharmacy are much brighter than they were a few years ago.

APPENDICITIS AND LEAD POISONING DUE TO INGESTION OF SHOT.

AMONG the foreign bodies which have been found in the appendix are shot. In the *Journal of the American Medical Association* of April 25th Dr. F. W. Hitchings and Dr. H. G. Sloan have recorded a case which is remarkable in several respects. A single woman, aged 21 years, was seen at midnight on Jan. 3rd, 1914. She said that 48 hours previously she had four teeth extracted under nitrous oxide anæsthesia. Twenty-four hours later she had a chill with vomiting which persisted almost until she was seen. She complained of severe pain all over the abdomen with occasional paroxysms. On examination the abdomen was generally tender, slightly more so over the appendix than elsewhere. The pulse was 74 and the temperature 98·9° F. On questioning the patient the following history was obtained. About Christmas, 1912, a number of cases of an eruption termed "Cuban itch" occurred in the town in which the patient lived. She contracted it and was treated without effect by several practitioners. A friend advised her that bird-shot was a "sure cure," and she took from 15 to 20 small bird-shot every morning until she had ingested about half a pound in all. The eruption disappeared, but some time later symptoms of lead poisoning—headache, colic, blue line on the gums, and digestive disturbances—appeared. In July, 1913, she suffered from severe convulsions, which almost proved fatal. They lasted a week and recurred at intervals until September. After this she had almost constant attacks of colic, nausea, vomiting. In spite of this experience she began to take shot again in November for a new kind of eruption on the face. This time she chose large shot. The dose was five or six every morning until a tablespoonful was taken. She asserted that she passed all she took. On Jan. 4th, 1914, the abdominal tenderness had increased and was great over the appendix. The pulse was 100 and the temperature was 99·3°. Acute appendicitis was diagnosed. A long median incision was made and the appendix was found to be inflamed, particularly at the tip, and heavy. It weighed 125 grains and contained eight shot. About a week after the operation 40 shot were passed per rectum and were much eroded. The urine contained a trace of albumin and a few hyaline and granular casts. The abdomen was radiographed but no more shot could be seen.

THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY.

WHEN reviewing the eighteenth volume of the second series of the Index Catalogue of the Library of the Surgeon-General's Office, United States Army,[1] we took occasion to state that the assiduous and patient labour of the army medical officers who produce that storehouse of remarkably accurate bibliographical, antiquarian, medico-historical, scientific, and professional lore—for by its arrangement and methods it is much more than a mere inventory of books—lays all medical scholars under a debt of gratitude to the Government of the United States. It is with something like dismay, therefore, that we learn through the protests now appearing in the American medical press that it is proposed this year to deprive this great library (which owes its world-wide eminence to the organising capacities and indefatigable energy of the late Dr. John Billings) of its independent status, and to transfer it to the library of Congress, constituting it a subordinate department thereof. Whatever may be the non-medical advantages expected to accrue from such a course, we fear that its results would be most regrettable for medical literature throughout the world. We cordially sympathise, therefore, with the protests of our American contemporaries, and trust that wiser counsels even yet may prevail.

THE PASTEURISATION OF MILK IN NEW YORK.

Dr. W. H. Guilfoy, Registrar of Records in the Department of Health, New York City, has recently compiled from the official statistics of his department a table of the mortality rate of children under 5 years of age in the boroughs of Manhattan and the Bronx, formerly the "Old City," one of the most insanitary districts in New York. In the year 1891, before the first Nathan Straus's pasteurised milk station was opened, the death-rate of children under 5 years of age was 96 per 1000. Within five years the corresponding mortality rate was reduced from 96 to 69; in another five years to 60, and in the next quinquennial period to 55. Last year the death-rate was reduced to the satisfactory level of 37. The fall in the death-rate of children under 5 years of age shows still more satisfactory results when the statistics for the fatal months of June, July, and August are taken separately. During these months before the year of introduction of pasteurised milk the mortality from epidemic diarrhœa was very high. In 1891 the rate was as high as 125 per 1000 per annum; in 1913, 22 years after the introduction of pasteurised milk, it fell to 38—truly a remarkable result. It naturally cannot be claimed that this gratifying improvement is exclusively due to the pasteurising of the milk, for many simultaneous and important improvements in sanitation and mothercraft generally have been introduced during this period. But it does seem to point to the fact that pasteurisation of milk is not incompatible with a low death-rate among young children as well as among infants. These statistics are on a large scale and at any rate should receive consideration from those enthusiasts for raw milk who maintain that the cooking of milk, not only has an injurious influence on the nutrition of infants under one year, but that it also has far-reaching influence in the same direction during the succeeding years of life.

THREE former students of King's College Hospital hold at the present moment the important posts of Director-General Navy Medical Department (Surgeon-General Arthur W. May, C.B.), Director-General Army Medical Service (Surgeon-General Sir Arthur T. Sloggett, C.B.), and Medical Inspector H.M. Prisons (Sir Herbert Smalley, M.D.). It is proposed to commemorate this unique occasion by entertaining them at dinner on Tuesday, June 16th, at the Waldorf Hotel. Viscount Hambleden, chairman of the committee of management of King's College Hospital, will take the chair at 7.30 P.M.

MR. Thomas H. Kellock, surgeon to the Middlesex Hospital, has announced his intention of standing as a candidate for the Council of the Royal College of Surgeons of England. Mr. Clement Lucas's resignation from the Council, which was noted in our columns last week, brings the number of vacancies to be filled in July next up to five, while the candidates now number 12.

THE library and offices of the Royal Society of Medicine will be closed for the Whitsuntide holidays from to-day Saturday, May 30th, to Tuesday, June 2nd, both days inclusive.

ST. LUKE'S HOSPITAL, PEKING.—Mr. Charles S. Rivington states in his report for 1913 that this hospital, which hitherto has been closed for some weeks during the New Year season, was open during the whole year. The work done shows a general increase. There were 162 in-patients, 5720 out-patients, and 149 operations with three deaths. Valuable financial help has been given by the Society for the Propagation of the Gospel in Foreign Parts towards the support of beds.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on May 21st, Sir Francis H. Champneys being in the chair. A letter was considered from the executive subcommittee of the Nursing and Midwifery Conference forwarding a copy of a resolution passed unanimously at the midwifery session of the conference on April 30th. suggesting that the Board should impose some definite qualifications guaranteeing the efficiency of an inspector of midwives. The board decided that the executive committee be informed that inspectors of midwives are not subject to the jurisdiction of the Board. A letter was considered from the London County Council suggesting that the register of cases to be kept by a midwife as prescribed by Rule E.23 should specifically provide a space in which to record the pulse and temperature of the patient. The Board decided that the reply be that this question has been considered by the Board, which thinks that the records of pulse and temperature are too numerous to be conveniently entered in the register and that the best way of recording them is in a separate book properly devised. A letter was considered from the National Association of Midwives (Manchester) forwarding a copy of a resolution passed unanimously at a meeting held on April 27th, urging that every facility should be given for the full and complete training of midwives so as to enable them to deal with every emergency arising in childbirth. The Board decided that the association be informed that the Board does not approve the suggestion.

MEDICINE AND THE LAW.

The Royal Society for the Prevention of Cruelty to Animals and the Runcorn Research Laboratories.

AN inspector of the Royal Society for the Prevention of Cruelty to Animals appealed recently to the Divisional Court against a decision of the justices of the county of Chester dismissing a summons taken out against Dr. Warrington Yorke, director of the Runcorn Research Laboratories at Crofton Lodge. The summons had charged the defendant with unlawfully and cruelly causing unnecessary suffering to a donkey by omitting to give it proper and necessary care and attention when in a suffering state. The magistrates dismissed the case on the facts, holding that the animal did not suffer unnecessary pain in the circumstances proved to have existed, and taking into consideration that the defendant was licensed to conduct the experiment in question. The appeal was dismissed by the Divisional Court on the ground that there was no point of law involved in the decision and that the justices had found as a fact that the respondent had not caused unnecessary suffering as charged against him in the summons. Their lordships did not call upon counsel for the respondent to argue the case on his behalf. The facts of this case were that the defendant, Dr. Yorke, and Dr. B. Blacklock were experimenting with antimony trioxide with a view to testing its therapeutic value in the treatment of experimental trypanosomiasis. An intramuscular injection in the gluteal region with a view to ascertaining the maximum dose of the drug was followed in the donkey, the subject of the summons, by necrosis of the muscle, with the result that its hind legs became paralysed and it lay down in the field. It was seen by Dr. Yorke at frequent intervals, and given food and water by the laboratory assistants. It was in a field surrounded by a wall, with a footpath at one corner. The defendant, on being visited by a policeman who complained of the condition of the donkey, pointed out that he made the experiment under licence from the Home Office, and that he could not destroy the donkey as the result of the experiment was not ascertained. Later he refused to allow an inspector of the Royal Society for the Prevention of Cruelty to Animals to see the animal, which had been removed from the field, and recommended him to communicate with the Home Office or with one of its inspectors, giving him the name of Sir James Russell. Two days after the policeman's visit the animal was killed with a Greener gun. Three weeks later a summons was taken out against Dr. Yorke, which was dismissed as stated. Sir Frederick Norman, chairman of the bench, then commented upon the manner in which the case had been presented by the society and upon the society not having communicated with the Home Office as suggested by the defendant. The Bench at that time refused to state a case for the consideration of the Divisional Court, on the ground that no point of law was involved, but apparently agreed to do this later, with the result that their original opinion was upheld. Dr. Yorke and his colleague are to be congratulated upon the result now established, but the Royal Society for the Prevention of Cruelty to Animals do not appear in the case in a favourable light. It is unnecessary to dwell upon the fact that the interests of animals, no less than human beings, are being served by the particular class of experiments referred to in this case. Upon more general grounds it must be pointed out that all experiments on animals are subject to the strict inspection and supervision applied by the State for the purpose of preventing the very conduct with which the society here charged the experimenter. That body had the opportunity to lay the grounds of its complaint before the Home Office and to bring down an inspector to test and to affirm if they were true the accuracy of the statements made, but it neglected to do so. It brought the defendant before police magistrates without calling any expert evidence either of an inspector or anyone else in support of its allegations, and after the facts had been found against it by the magistrates took the case up to the Divisional Court without having any substantial point of law to raise which would have justified it in doing so.

The Property in a Prescription.

Recently at the North London police-court a druggist was summoned for detaining a prescription. The complainant had had a prescription made up by a druggist whose business had been purchased by the defendant. The complainant asked to have the prescription handed back to him, and as this was refused took out the summons in order to obtain it. For the defence it was stated that so far as the defendant was concerned he only had a copy in the books of his predecessor which he had purchased with the business, and the magistrate, Mr. D'Eyncourt, observed that according to his experience the original document containing the prescription was usually returned by the druggist to the customer. The defendant after discussion offered to copy out the prescription and hand it to the complainant in return for a fee, but eventually he consented to do so without payment. It was suggested on behalf of the complainant that the copy should be cut from the book and handed over, but Mr. D'Eyncourt refused to order this to be done, saying that if there were any question of an infringement to be raised it was for the medical man who gave the prescription to raise it. The arrangement mentioned above having been arrived at the summons was withdrawn on the defendant paying 13*s.* 6*d.* costs.

Malingering under the Workmen's Compensation Act.

His honour Judge Amphlett in the Birmingham county court recently terminated an award of 4*s.* 6*d.* per week under which a girl was receiving compensation from her employers for the alleged results of an accident. Her story was that while following her occupation of a scissors-setter some filings flew into her eyes so that she had lost her sight and could follow no employment. According to her employers she was perpetrating a fraud upon them. Mr. W. Allport, who as medical referee had had the girl under observation, had succeeded in covering her eyes with metal discs in such a way that these would have shown if they had been tampered with. After being thus covered for a few days the eyelids had ceased to show signs of inflammation. The girl had resisted having her eyelids opened, but upon their being opened by force the lids and eyeballs were found to be normal and healthy. She had persisted in keeping her eyes closed when under observation in a nursing home, and when they had been forcibly opened had rolled her eyes upwards so that they had to be brought into a normal position with forceps for examination.

a week after the operation 40 shot were passed per rectum and were much eroded. The urine contained a trace of albumin and a few hyaline and granular casts. The abdomen was radiographed but no more shot could be seen.

THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY.

WHEN reviewing the eighteenth volume of the second series of the Index Catalogue of the Library of the Surgeon-General's Office, United States Army,[1] we took occasion to state that the assiduous and patient labour of the army medical officers who produce that storehouse of remarkably accurate bibliographical, antiquarian, medico-historical, scientific, and professional lore—for by its arrangement and methods it is much more than a mere inventory of books—lays all medical scholars under a debt of gratitude to the Government of the United States. It is with something like dismay, therefore, that we learn through the protests now appearing in the American medical press that it is proposed this year to deprive this great library (which owes its world-wide eminence to the organising capacities and indefatigable energy of the late Dr. John Billings) of its independent status, and to transfer it to the library of Congress, constituting it a subordinate department thereof. MEDICINE AND THE LAW.

The Royal Society for the Prevention of Cruelty to Animals and the Runcorn Research Laboratories.

AN inspector of the Royal Society for the Prevention of Cruelty to Animals appealed recently to the Divisional Court against a decision of the justices of the county of Chester dismissing a summons taken out against Dr. Warrington Yorke, director of the Runcorn Research Laboratories at Crofton Lodge. The summons had charged the defendant with unlawfully and cruelly causing unnecessary suffering to a donkey by omitting to give it proper and necessary care and attention when in a suffering state. The magistrates dismissed the case on the facts, holding that the animal did not suffer unnecessary pain in the circumstances proved to have existed, and taking into consideration that the defendant was licensed to conduct the experiment in question. The appeal was dismissed by the Divisional Court on the ground that there was no point of law involved in the decision and that the justices had found as a fact that the respondent had not caused unnecessary suffering as charged against him in the summons. Their lordships did not call upon counsel for the respondent to argue the case on his behalf. The facts of this case were that the defendant, Dr. Yorke, and Dr. B. Blacklock were experimenting with antimony trioxide with a view to testing its therapeutic value in the treatment of experimental trypanosomiasis. An intramuscular injection in the gluteal region with a view to ascertaining the maximum dose of the drug was followed in the donkey, the subject of the summons, by necrosis of the muscle, with the result that its hind legs became paralysed and it lay down in the field. It was seen by Dr. Yorke at frequent intervals, and given food and water by the laboratory assistants. It was in a field surrounded by a wall, with a footpath at one corner. The defendant, on being visited by a policeman who complained of the condition of the donkey, pointed out that he made the experiment under licence from the Home Office, and that he could not destroy the donkey as the result of the experiment was not ascertained. Later he refused to allow an inspector of the Royal Society for the Prevention of Cruelty to Animals to see the animal, which had been removed from the field, and recommended him to communicate with the Home Office or with one of its inspectors, giving him the name of Sir James Russell. Two days after the policeman's visit the animal was killed with a Greener gun. Three weeks later a summons was taken out against Dr. Yorke, which was dismissed as stated. Sir Frederick Norman, chairman of the bench, then commented upon the manner in which the case had been presented by the society and upon the society not having communicated with the Home Office as suggested by the defendant. The Bench at that time refused to state a case for the consideration of the Divisional Court, on the ground that no point of law was involved, but apparently agreed to do this later, with the result that their original opinion was upheld. Dr. Yorke and his colleague are to be congratulated upon the result now established, but the Royal Society for the Prevention of Cruelty to Animals do not appear in the case in a favourable light. It is unnecessary to dwell upon the fact that the interests of animals, no less than human beings, are being served by the particular class of experiments referred to in this case. Upon more general grounds it must be pointed out that all experiments on animals are subject to the strict inspection and supervision applied by the State for the purpose of preventing the very conduct with which the society here charged the experimenter. That body had the opportunity to lay the grounds of its complaint before the Home Office and to bring down an inspector to test and to affirm if they were true the accuracy of the statements made, but it neglected to do so. It brought the defendant before police magistrates without calling any expert evidence either of an inspector or anyone else in support of its allegations, and after the facts had been found against it by the magistrates took the case up to the Divisional Court without having any substantial point of law to raise which would have justified it in doing so.

The Property in a Prescription.

Recently at the North London police-court a druggist was summoned for detaining a prescription. The complainant had had a prescription made up by a druggist whose business had been purchased by the defendant. The complainant asked to have the prescription handed back to him, and as this was refused took out the summons in order to obtain it. For the defence it was stated that so far as the defendant was concerned he only had a copy in the books of his predecessor which he had purchased with the business, and the magistrate, Mr. D'Eyncourt, observed that according to his experience the original document containing the prescription was usually returned by the druggist to the customer. The defendant after discussion offered to copy out the prescription and hand it to the complainant in return for a fee, but eventually he consented to do so without payment. It was suggested on behalf of the complainant that the copy should be cut from the book and handed over, but Mr. D'Eyncourt refused to order this to be done, saying that if there were any question of an infringement to be raised it was for the medical man who gave the prescription to raise it. The arrangement mentioned above having been arrived at the summons was withdrawn on the defendant paying 13s. 6*d*. costs.

Malingering under the Workmen's Compensation Act.

His honour Judge Amphlett in the Birmingham county court recently terminated an award of 4*s*. 6*d*. per week under which a girl was receiving compensation from her employers for the alleged results of an accident. Her story was that while following her occupation of a scissors-setter some filings flew into her eyes so that she had lost her sight and could follow no employment. According to her employers she was perpetrating a fraud upon them. Mr. W. Allport, who as medical referee had had the girl under observation, had succeeded in covering her eyes with metal discs in such a way that these would have shown if they had been tampered with. After being thus covered for a few days the eyelids had ceased to show signs of inflammation. The girl had resisted having her eyelids opened, but upon their being opened by force the lids and eyeballs were found to be normal and healthy. She had persisted in keeping her eyes closed when under observation in a nursing home, and when they had been forcibly opened had rolled her eyes upwards so that they had to be brought into a normal position with forceps for examination.

A NEW WATER RESERVOIR AT SOUTHEND.

(FROM A CORRESPONDENT.)

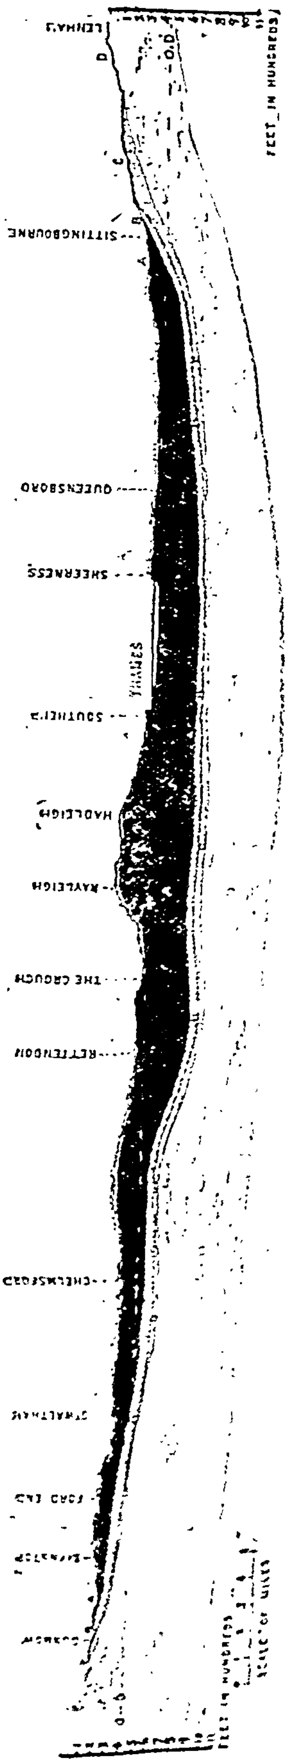
AT Vange, some 10 miles distant from Southend, there has recently been completed the first half of what will be eventually one of the largest covered reservoirs in the United Kingdom. This section is capable of storing not less than 17 million gallons of water. The population of Southend and the adjacent district is multiplying rapidly, and those who realise the difficulty attendant upon obtaining a large quantity of water suddenly for a community will appreciate the foresight of the water company.

Though the reservoir is an underground one, the bottom is above the drainage level of the neighbouring watercourses, thus reducing the risk of local pollution. The clay from the excavation has been used to form the puddled embankment necessary to impound this huge volume of water, covering some 4 acres to a depth of 25 feet. The floor is of concrete, while the sloping sides of the retaining embankments are lined internally with artificial stone slabs. A series of dividing walls formed of brick arches cross its width, to support the longitudinal girders carrying the roof, which last is formed of reinforced concrete. The pumping-house, inspection chamber, and provisions necessary to ensure immunity from possible pollution have been carefully considered, to secure a supply of pure water for a population never less than 100,000, and during the summer months probably 150,000. The old reservoirs at Thundersley and elsewhere, containing 7½ million gallons of water, have been retained, and all water is supplied direct to the consumer without previous treatment. There are in all 26 wells, some being of great depth, passing down to the chalk to a total depth of 900 feet. In order to obtain the necessary supply these wells are placed at great distances apart, covering in all a radius of about 20 miles, necessitating some 160 miles of mains, trunk and distributory. Each well has a separate pumping station.

The Cause of the Softness of the Water.

The expense connected with obtaining such a large supply under these difficult conditions has been very great. The overlying clay mantle in many places is known to be 500 feet thick, and is, of course, impervious to water. It is this unfavourable geological formation, together with the chemical peculiarities of the water, that give special interest to this particular water-supply. The chalk, from which some of the water is drawn, is overlain by the Thanet sands, forming the bottom bed of the London tertiaries. It is therefore only at its outcrop, on the north round Colchester and Braintree, and on the south in the neighbourhood of Grays and in Kent, that the rainfall can find access and maintain the supply to this great reservoir of the London basin. The rain water, charged with carbonic acid falling upon the chalk, dissolves calcium carbonate to an extent that produces in wells near the outcrop a hardness of 31·0, while the same water when reaching mid-Essex and the south-eastern district is almost alkaline, having but 1·8 degrees of hardness, due to the presence of sodium carbonates and sulphates. Now it is known that sea water percolates through fissures in the chalk, so much so that certain wells at a distance from the coast have had to be abandoned owing to the excess of sodium chloride present in the water. This percolation from the sea is thought to account for the large amount of sodium chloride frequently present in mid-Essex water, varying considerably in different localities. However, unlike the calcium salts of the hard water, which seem to be replaced by salts of sodium (carbonate and sulphate) in the soft water, the sodium chloride bears no relation to the other salts present. The point of interest is the gradual increase in the softness of the water as it approaches the point of greatest depth of clay. Dr. J. C. Thresh, medical officer of health to the Essex county council, who has devoted great attention to the subject, accounts for this by the following theory. The immense mass of clay compresses the chalk in proportion as it approaches its greatest depth, rendering the chalk impervious to water or nearly so. Thus water falling on the outcrop at first dissolves the chalk-forming fissures until the acid is exhausted. The water

Section Illustrating the Geological Conditions on which Dr. Thresh bases his Conclusions.



A, London clay of varying thickness, excluding the rainfall between Dunmow on the north, and the district round Rochester, Lenham, and Charing on the south, at which places the chalk comes to the surface. The clay is covered with alluvial deposits, boulder clay, Bagshot sands, &c., in varying quantities.
B, The Woolwich and Reading beds, some impervious, others porous to some extent, from 20 feet to 90 feet thick.
C, Thanet Sands. It is thought that in the Eocene epoch these were derived from flints, the composition of which is silica chemically deposited round some siliceous sponge or other similar nucleus. They are associated with glauconite grains whose chemical constituents tend to reduce any hardness due to calcium carbonate.
D, Chalk. This, on the north-west, rises to the higher elevation round Saffron Walden, and is some 1000 feet thick, while towards the south its surface has been denuded, and finally ends abruptly in the south-east in an escarpment overlooking the weald of Kent and Sussex, where it is only some 300 feet thick. Its trend is upwards, and in Eocene times it rose to form the lofty anticlinal over the weald, falling to join the Sussex downs. The denudation of this dome, it is supposed, provided most of the material for the formation of the London tertiaries. O.D., Ordnance datum.

then recedes from the outcrop along the top of the chalk through the Thanet sands towards the centre of the great mass of clay, and owing to increased compression and loss of acid is unable to soak deeper into the chalk and rests in the Thanet sands above. These sands have a varying thickness of 10–40 feet. According to the theory of Dr. Thresh, in which he is supported by Bischoft in his "Chemical and Physical Geology," "calcareous water passing through certain silicates of alumina containing potash and soda become softened." Such silicates are present in the Thanet sands in the form of glauconite, a hydrous silicate of aluminium, iron (in the condition of peroxide), potassium, magnesium, and calcium.[1] Glauconite is the soft earthy substance found in shells of foraminifera, which when present in great quantities forms greensands and glauconite limestone.

Dr. Thresh proved the softening property of these sands by experiment, but found that though the softening power was lost after long contact with a hard water this could be reinstated by contact with a saline water such as would be supplied by infiltration from the sea. In another experiment, by mixing water composed of similar constituents to sea water with one hardened by calcium carbonate, &c., similar in composition to water drawn direct from the chalk and afterwards passing the same through a greensand filter, a water was produced similar in its chemical constituents to the deep well water of central and south-east Essex. This theory seems to prove that the extreme softness of the water supplied to the Southend district is due to two circumstances: the compression of the water in the Thanet sands above the chalk acting as a softening filter, and the renewal of the softening properties contained in these sands by the presence of sea water due to percolation.[2]

The following is an analysis of No. 1: the soft water supplied to Southend. No. 2: ordinary sea water. No. 3: hard water drawn directly from the chalk:—

No. 1.—Southend Water.

	Grains per gallon.
Calcium carbonate	1·2
Magnesium carbonate	0·4
Sodium carbonate	21·0
Sodium sulphate	9·1
Sodium chloride...	22·7
Silica, &c.	0·9
	55·3

No. 2.—Sea Water.

	Per cent.
Sodium chloride...	78·32
Magnesium chloride	9·44
Magnesium sulphate	6·40
Calcium sulphate	3·94
Potassium chloride	1·69
Other substances, including calcium carbonate and silica	0·21
	100·00

No. 3.—Hard Chalk Water.

(Manningtree, North Essex.)

	Grains per gallon.
Calcium carbonate	16·4
Magnesium carbonate	4·5
Magnesium sulphate	5·0
Magnesium chloride	1·3
Sodium chloride	16·0
Silica, &c.	1·2
	44·4

The chalk water at Manningtree undoubtedly contains a trace of sea water, and it will be seen that if most of the calcium and magnesium salts were converted by the action of the Thanet sand into the corresponding salts of sodium, a water identical in character with the Southend water would result. Such soft, alkaline waters appear to be excellently adapted for drinking and general domestic purposes.

A GENERAL TUBERCULOSIS SCHEME FOR LONDON.

THE Public Health Committee on May 26th presented to the London County Council a complete scheme for the treatment of tuberculosis amongst the uninsured population of the metropolis which it has had in preparation since February, 1913. In the interval, as we have noted from time to time,[1] the relations between the County Council, the Metropolitan Asylums Board (as the infectious diseases authority in London), and the London Insurance Committee have been defined, and a beginning has been made with the organisation of dispensary treatment, several local schemes having been approved.

In outlining its scheme the Public Health Committee stated that it was anxious to encourage the provision of a complete network of dispensaries, as it had been much impressed with the potential value of these institutions as a means of discovering contact cases at an early stage and as a necessary first unit in any complete scheme. The committee had tried also to make the fullest possible use of the many agencies already available, and so to frame the scheme as to secure the coöperation of the great London hospitals. The Council's efforts would be most usefully directed to linking up all the various existing agencies and others to be created. It should use its funds to encourage the provision of fresh accommodation and to keep open institutions which might otherwise be closed, for the committee had come to the conclusion that adequate provision could be made through existing authorities, and that the Council itself need not own or manage institutions. Special attention should be given to the provision of residential accommodation for tuberculous children, for in this direction expenditure in treatment would be most profitably incurred.

Domiciliary treatment the committee dismissed in a few words with an allusion to the provision made under the Insurance Act and the statement that "domiciliary treatment of uninsured persons is provided by private practitioners, district medical officers, and voluntary institutions, and, in so far as it may be incidental to dispensary treatment, by the medical officer of the dispensary." Apparently financial assistance in uninsured domiciliary cases is not contemplated. Dispensary treatment would be provided by the borough councils, the County Council paying half the cost in the case of uninsured persons, subject to a condition, amongst others, that the dispensary would be linked up with a hospital. (The whole of these conditions were published in THE LANCET of Nov. 22nd, 1913, p. 1481.) Arrangements would be made by the County Council for the provision of residential accommodation for (1) observation, (2) hospital, (3) sanatorium, and (4) chronic or advanced cases.

An Honorary Tuberculosis Advisory Board.

For the purpose of selecting patients (uninsured) for residential treatment there should be established an honorary advisory board consisting of—

(a) One representative appointed by each of the teaching and other general hospitals and children's hospitals which are acting in any capacity under the scheme.

(b) Two representatives appointed by each of the three special chest hospitals.

(c) The medical superintendent appointed by each of the sanatoriums with which arrangements have been made by the Council.

(d) Two representatives of the tuberculosis dispensaries.

(e) The medical officer and deputy medical officer of health appointed by the County Council.

The board would be empowered, with the consent of the Council, to coöpt persons possessing special medical or surgical knowledge. The representatives appointed by the teaching and general hospitals should be physicians and assistant physicians actively engaged in hospital practice. The honorary advisory board would be asked to prepare a memorandum as to the types of cases suitable for the various forms of institutional treatment, this to be circulated to the medical officers and institutions dealing with the cases. The board should advise as to forms for medical reports and generally as to all matters upon which uniformity was desirable or upon which the Council might desire to have its opinion. The advisory board should appoint from its own body, or, if thought desirable, from outside, a rota of two or more physicians to act as medical referees and to examine all cases referred to them by the medical officer of the county in accordance with conditions to be prepared by the advisory board and approved by the Council. These physicians would attend as required at a limited number of convenient centres for the purposes of examining cases, advising the county medical officer and recommending as to the action to be taken. Each physician while on the rota would be paid an honorarium of one guinea for each case. Representatives on the advisory board of sanatoriums, dispensaries, and the County Council would not be eligible to serve on the rota.

---

[1] For analysis see "Report on the Deep Sea Deposits," Challenger Reports, 1891, p. 387.

[2] THE LANCET, Feb. 3rd, 1912, p. 315.

[1] THE LANCET, Feb. 15th (p. 478), March 15th (p. 785), and Oct. 25th (p. 1205), 1913.

The committee anticipated that the advisory board would be of great assistance in advising the Council generally on all matters necessary to secure smooth working and useful coöperation amongst the different institutions taking part in the scheme. Although this proposal was new to the Council, the committee had had the advantage of conferring upon it with representatives of the principal London hospitals, and a resolution was passed by a large majority in which the representatives expressed general approval of the proposals and their intention to advise their several hospitals to appoint members on the advisory board.

Organisation of Treatment.

It should be referred to the dispensary medical officer to classify the cases clinically as suitable for home treatment, consultative reference to hospitals, in-patient hospital treatment or sanatorium treatment, and to forward to the medical officer of health for the borough a report on each case. The local medical officer of health would then classify the cases as to home conditions in three classes—(*a*) satisfactory, (*b*) unsatisfactory, and (*c*) removal urgently necessary. In cases recommended for in-patient hospital treatment or sanatorium treatment, the papers would be forwarded to the county medical officer, and he would refer to the rota all cases in which the advice of the referees was required. The judgment of the medical referees would not be subject to clinical review by the Council. Children suffering from tuberculosis would be grouped under the following classes: those suffering from (1) bone and joint tuberculosis; (2) pulmonary tuberculosis; (3) tuberculosis of the skin, glands, and other organs; and (4) suspects—i.e., cases noted by bacteriological methods to be tuberculous or found on medical examination to be predisposed to the disease and presenting signs pointing to the possibility of the disease in an incipient form. About 1500 children of the first class were in attendance at schools for the physically defective, and the remainder might be classed as in-patients or out-patients at London hospitals. Some pulmonary cases could be dealt with in open-air day schools; those cases which needed residential treatment might be met by making arrangements for the children to sleep at night at open-air schools. The glandular cases presented little difficulty; a small number would require a stay in the country, the others could be dealt with in open-air schools and tuberculosis dispensaries. In this matter the school medical work must be coördinated. In the course of medical inspection all cases of tuberculosis not notified to the local medical officers of health should be notified to the county medical officer. Arrangements must also be made for after-care and the preservation of records.

In regard to the general provision of residential accommodation, the Public Health Committee considered that, as most of those for whom the Insurance Committee made provision were males, the Council would find that most of the adults for whom it would be responsible would be women. It was more difficult in the case of adults than of school children to frame a reliable estimate of numbers, but probably by April, 1915, for adults 160 beds would be required in hospitals and 240 beds in sanatoriums, with an initial provision for children of 150 beds in residential institutions. So far as hospital beds were concerned there was accommodation at reasonable prices almost sufficient for the needs of the immediate future, but this was not the case with sanatorium beds either for adults or children. The Council should encourage existing institutions to increase their accommodation. Subject in some cases to adjustment of questions still under discussion, beds could be obtained at the Brompton, City of London (Victoria Park), King's College, Metropolitan, Royal Chest (City-road), Royal Free, St. Bartholomew's, St. Mary's, University College, and Westminster Hospitals, and the Fairlight (Hastings), Frimley, Whitmead (Surrey), and Maltings Farm (Suffolk) Sanatoriums. The authorities of King's College Hospital were prepared to place at the Council's disposal when ready a new ward containing 24 beds, the cost to the Council being £1600 a year. This offer the committee proposed to accept. The sanatorium accommodation available was considerably below the Council's requirements, but it was hoped that a number of additional beds would be obtained from institutions which at present asked more than 30*s.* a week for a bed. Even then many more beds would be needed, and the Metropolitan Asylums Board had been asked on what terms it could provide 150 beds, which would be a suitable initial provision. There were in Poor-law institutions about 2300 advanced or chronic cases of tuberculosis. If the Council provided for these cases one-half of the cost would be borne by the Exchequer instead of by the rates as at present. On grounds of convenience the committee had asked the Metropolitan Asylums Board to deal with these cases on its behalf, and perhaps to take over some of the infirmaries. The committee had fixed 20*s.* as a proper weekly charge in respect of residential accommodation for tuberculous children. Arrangements were pending with the East Anglian Sanatorium, Nayland, for 50 beds and the Victoria Home, Margate, for five beds, and the Metropolitan Asylums Board had been asked to provide accommodation. The East Anglian Sanatorium would provide 50 additional beds, and offered to supply 50 beds in tents until permanent structures were ready. Negotiations were proceeding with the authorities of the Alexandra Hospital for the erection of a children's convalescent home near London. As explained above, the greater part of the accommodation required for children would be supplied by the children's hospitals and the physically defective schools.

In regard to after-care the scheme provided that the local medical officer and the private practitioner should be notified of the discharge of an adult patient from a sanatorium. In all cases in which a patient or the person legally responsible for a patient was in receipt of an income of £160 a year or over, and the circumstances appeared to justify the demand, a charge should be made for treatment received. As a condition of receiving residential treatment a patient would be required to give an undertaking to remain under medical supervision on his discharge. On the question of cost the committee gave the following estimate:—

	Cost for 1914-15.	Cost for 1915-16.
Hospital beds (160)	£ 8,928	£12,480
Sanatorium beds (240)	13,439	18,720
Children's beds (150)	5,454	7,650
Travelling and incidental expenses, including fees of medical referees ...	1,100	1,400
	28,921	40,250
	(Say) 29,000	(Say) 40,000
Government contribution	14,250	20,000
Fees of medical referees, payable by borough councils	500	—
Net estimated expenditure	£14,250	£20,000

Discussion.

After a short debate the Council approved the scheme. Mr. O. E. WARBURG, chairman of the committee, emphasised the point that the intention to make the dispensary the essential unit of the machinery was in accord with the report of the departmental committee. Whenever a patient attended a dispensary a visit would afterwards be paid to his home to see the conditions under which he was living. In the second unit of the scheme—residential accommodation—it was intended to make full use of the *knowledge* already possessed by the great hospitals, but the attempt was made to provide machinery by which the various agencies might be linked up.

Mr. J. A. DAWES, M.P., chairman of the London Insurance Committee, said that the one great blot on the scheme was that it dealt with uninsured persons only. Other counties and large boroughs had taken a broad view and had undertaken the treatment of the whole tuberculous population, the Insurance Committees handing over their patients and available funds to the county councils. Only thus could a comprehensive and entirely satisfactory scheme be prepared for London. It was unfortunate that for dispensary purposes there were 29 "ring-fence" areas—the boroughs—in some of which there were municipal dispensaries and in others dispensaries provided by voluntary effort, whilst in some the borough councils had refused to deal with the matter at all. In 10 or 12 boroughs nothing had been done beyond the passing of pious resolutions. The general scheme was a very great step in providing residential accommodation, but he was afraid the committee had seriously underestimated the number of beds required in hospitals and sanatoriums.

THE INFECTIVITY OF PULMONARY TUBERCULOSIS.

THE STATEMENT BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

IN our issue of April 11th, 1914, in the report of the meeting of the Comitia of the Royal College of Physicians of London, we referred to the adoption of the report of a subcommittee of five members upon the infectivity of tuberculosis. This report, of which we gave a summary, has been issued by the College in the form of a statement which is designed to render assistance to those having administrative duties in connexion with tuberculosis. At the request of several correspondents we now print the statement in full. It has been drawn up in the hope that medical men in private practice will base on it a common procedure in giving advice and instruction about the infectivity of tuberculosis, and that medical officers of health may find it useful in connexion with administration. The statement is specifically issued by the Royal College of Physicians "in view of the exaggerated fear of the infectivity of pulmonary tuberculosis entertained by the public." Copies may be had on application to the Registrar of the College, Pall Mall East, London, S.W.

The Infectivity of Tuberculosis.

1. Tuberculosis is an acquired disease, but certain constitutional types may be inherited which render the patient specially susceptible to infection, and there is reason to think that such susceptibility is an inherited character.

2. The infective agent is the tubercle bacillus. This may be contained in the various discharges and excreta of the patient, and especially in the sputum of those suffering from pulmonary tuberculosis. No discharge is infective unless it contains the tubercle bacillus.

3. Cases of tuberculosis of bones, glands, and internal organs from which there is no discharge or which do not furnish any excretion, and cases of arrested pulmonary tuberculosis, have never been proved to be infectious.

(By arrest is here meant that all the symptoms and physical signs of activity have disappeared, and the sputum has either ceased or no longer contains tubercle bacilli.)

4. The means by which tubercle bacilli may enter the body are:—

(*a*) *By inoculation* through a wound or abrasion of the skin. This has occasionally occurred to workers in laboratories, post-mortem attendants, and others dealing with tuberculous material, and is presumably the way in which lupus is acquired.

(*b*) *By inhalation.* Susceptible animals are readily infected by the inhalation of air containing tubercle bacilli, whether in droplets or suspended as fine dust, but in the spread of the disease among human beings the latter appears to be the more important means of infection. The sputum or other discharges, whether on soiled handkerchiefs, linen, garments, or elsewhere, when dried, may become pulverised, and in this condition may be readily dispersed in the air of a room. That droplets of sputum are less important agents of infection is suggested by the fact that the incidence of consumption upon the staff, nurses, and others engaged in hospitals for the treatment of tuberculous disease, where all discharges are carefully disposed of, is not above the average in the general population.

(*c*) *By swallowing.* Dust infected by the tubercle bacillus may be conveyed to food and so enter the alimentary canal; or infection may occur more directly in the act of kissing or by consumptive and healthy persons using the same food utensils. As about 10 per cent of the milk supplied to large cities contains tubercle bacilli derived from infected cows, this avenue of infection is particularly important in the case of children. The bovine tubercle bacillus is more commonly responsible for tuberculosis in young children than in adults, but the proportion of cases due to it varies very much in different localities.

There is no evidence that tuberculosis can be conveyed to others either by the breath alone, or by emanations from patients, or by their garments, unless soiled by dried sputum or discharges.

5. The spread of tuberculosis is favoured by uncleanliness, overcrowding, and imperfect ventilation, and is hindered by the opposite conditions. Experience in hospitals and other institutions where the following precautionary measures have been thoroughly carried out indicates that by such measures the risk of infection is reduced to a minimum, namely—

(*a*) The careful disposal and disinfection of the sputum and other discharges.

(*b*) The disinfection or destruction of soiled handkerchiefs, clothes, and linen.

(*c*) The removal of dust by frequent moist cleansing of the floors, walls, &c., of the rooms.

(*d*) The supply of abundant air space, and free ventilation with fresh air.

No risk is incurred by living in the immediate neighbourhood of institutions for the treatment of tuberculosis which are properly conducted.

ROYAL COMMISSION ON VENEREAL DISEASES.

EVIDENCE was given at the thirty-sixth meeting of the Royal Commission on Venereal Diseases by Sir T. Clifford Allbutt, Regius Professor of Physic in the University of Cambridge.

Sir Clifford Allbutt, whose evidence related mainly to arterial disease, stated that syphilis was by far the gravest of the infectious diseases of the arteries, and that it was particularly grave in its tendency to cause aneurysms of which probably 95 per cent. were syphilitic. He thought it probable that, if infection with syphilis were dealt with at an early stage and by the most modern methods of treatment, the occurrence of these syphilitic diseases of the arteries might be avoided. In cases where syphilitic disease of the aorta did occur it was of enormous importance that it should be dealt with at the earliest possible moment and with the greatest and promptest vigour.

At the thirty-seventh meeting evidence was given by Mrs. R. P. Wethered and Miss Amy Hughes, representing a large and representative meeting of ladies interested in rescue work which was held some time ago under the presidency of Her Royal Highness Princess Christian. At this meeting the following resolution was passed:—

> That this meeting, consisting of rescue workers, matrons of hospitals and workhouses, district nurses, lady guardians, and others, advocates a system of confidential notification (by doctors) to a specially appointed sanitary authority as the only means of altering the law of libel and so ensuring proper precautions being taken against danger to the community, and especially to innocent persons.

Mrs. Wethered submitted to the Commission particulars of a number of cases which had occurred in her experience illustrating the necessity of telling the truth with regard to this matter and of recognising the infectious nature of these diseases.

DONATIONS AND BEQUESTS.—The Hospital for Consumption and Diseases of the Chest, Brompton, has received a donation of £500; the Prince of Wales's General Hospital, Tottenham, £250; and the Chelsea Hospital for Women £500 towards its rebuilding fund, and £100 towards the funds of its convalescent home at St. Leonards-on-Sea from the trustees of Smith's (Kensington Estate) Charity. The same charity has sent £200 to Queen Charlotte's Hospital, Marylebone-road.—The late Mr. Frederick Burton, of Hopefield, Pendleton, and Gwaynynog, Denbigh, and treasurer of the Salford Royal Hospital, has left £2000 to the Salford Royal Hospital, £1000 to the Manchester Royal Infirmary, £1000 to the St. Mary's Hospitals, Manchester, and £500 to the Denbigh Infirmary.—Mr. Edward Graham Wood, of Salford and Southport, has presented to the Southport Infirmary £1000 to endow a bed, to be called the Kenneth Graham Holden Bed. This is the fifth hospital bed which Mr. Wood has endowed in Lancashire.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8500 births and 4834 deaths were registered during the week ended Saturday, May 23rd. The annual rate of mortality in these towns, which had declined from 15·1 to 14·1 per 1000 in the four preceding weeks, further fell to 13·9 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 14·5, against 13·6 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 5·1 in Ealing, 6·2 in Leyton, 6·4 in Reading, 6·9 in Ilford, and 7·5 in Eastbourne, to 20·2 in Oxford, 20·5 in Sunderland, 21·0 in Middlesbrough, 21·1 in West Hartlepool, and 22·0 in Stockton-on-Tees.

The 4834 deaths from all causes were 71 fewer than the number in the previous week, and included 468 which were referred to the principal epidemic diseases, against numbers declining from 453 to 421 in the three preceding weeks. Of these 468 deaths, 144 resulted from whooping-cough, 143 from measles, 83 from infantile diarrhœal diseases, 51 from diphtheria, 34 from scarlet fever, and 13 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3, against 1·3 and 1·2 per 1000 in the two preceding weeks. The deaths attributed to whooping-cough, which had been 139, 146, and 143 in the three preceding weeks, were 144 last week, and caused the highest annual death-rates of 1·5 in Stoke-on-Trent, 1·6 in Barrow-in-Furness and in West Hartlepool, and 1·7 in Walsall and in Newport (Mon.) The deaths referred to measles, which had been 155, 146, and 138 in the three preceding weeks, rose to 143 last week; the highest death-rates from this disease were 1·2 in Blackburn, in Middlesbrough, and in Newport (Mon.), 1·4 in Bootle, 2·0 in Dudley and in Sheffield, 2·1 in Warrington, and 2·8 in Rochdale. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 59, 59, and 69 in the three preceding weeks, further rose to 83 last week; of this number 17 were recorded in London, 10 in Liverpool, 9 in Manchester, and 3 each in Bristol, Birmingham, Salford, Sheffield, and Middlesbrough. The deaths attributed to diphtheria, which had been 50, 44, and 31 in the three preceding weeks, rose to 51 last week, of which 12 occurred in London, 5 in Birmingham, 4 in Leeds, and 2 each in West Ham, Walthamstow, Bradford, and Middlesbrough. The deaths referred to scarlet fever, which had been 35, 27, and 33 in the three preceding weeks, were 34 last week, and included 6 in London, 5 in Liverpool, 4 in Manchester, and 2 each in Birkenhead, Oldham, Sheffield, and Newcastle-on-Tyne. The fatal cases of enteric fever, which had been 15, 13, and 7 in the three preceding weeks, rose to 13 last week, of which 3 occurred in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 2876, 2901, and 2862 at the end of the preceding three weeks, had increased to 2909 on Saturday last; 415 new cases were admitted during the week, against 377, 398, and 349 in the three preceding weeks. These hospitals also contained on Saturday last 1125 cases of diphtheria, 363 of whooping-cough, 100 of measles, and 47 of enteric fever, but not one of small-pox. The 1097 deaths from all causes were 59 fewer than the number in the previous week, and corresponded to an annual death-rate of 12·7 per 1000. The deaths referred to diseases of the respiratory system, which had been 185, 221, and 190 in the three preceding weeks, further declined to 188 last week, and were 9 below the number recorded in the corresponding week of last year.

Of the 4834 deaths from all causes in the 97 towns, 169 resulted from various forms of violence, and 363 were the subject of coroners' inquests, while 1433 occurred in public institutions. The causes of 37, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Sheffield, Leeds, Bristol, Bradford, Hull, and in 55 other smaller towns. Of the 37 uncertified causes of death, 8 were registered in Birmingham, 6 in Liverpool, 3 in Portsmouth, 2 in Leicester, and 2 in Nottingham.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1258 births and 709 deaths were registered during the week ended Saturday, May 23rd. The annual rate of mortality in these towns, which had been 15·2, 16·2, and 15·3 per 1000 in the three preceding weeks, rose to 16·1 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 16·0, against a corresponding rate of 14·5 per 1000 in the 97 large English towns. Among the several towns the death-rate last week ranged from 3·1 in Falkirk, 8·8 in Kilmarnock, and 10·5 in Clydebank, to 16·9 in Perth, 17·8 in Glasgow, and 24·3 in Hamilton.

The 709 deaths from all causes were 36 in excess of the number in the previous week, and included 62 which were referred to the principal epidemic diseases, against 64 and 55 in the two preceding weeks. Of these 62 deaths, 27 resulted from measles, 14 from infantile diarrhœal diseases, 10 from whooping-cough, 7 from scarlet fever, 3 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·4, against 1·3 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 19, 31, and 20 in the three preceding weeks, rose to 27 last week, of which 17 occurred in Glasgow, 4 in Dundee, 2 in Edinburgh, and 2 in Hamilton. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 17, 4, and 6 in the three preceding weeks, further rose to 14 last week, and included 10 in Glasgow. The fatal cases of whooping-cough, which had increased from 9 to 15 in the four preceding weeks, declined to 10 last week, and comprised 7 in Glasgow, 2 in Coatbridge, and 1 in Dundee. The deaths attributed to scarlet fever, which had been 2, 4, and 4 in the three preceding weeks, rose to 7 last week, of which 3 occurred in Glasgow, 3 in Edinburgh, and 1 in Motherwell. The deaths referred to diphtheria, which had declined from 9 to 5 in the four preceding weeks, further fell to 3 last week, and were recorded in Glasgow, Aberdeen, and Paisley. The fatal case of enteric fever was registered in Glasgow. In addition to the above a death from typhus occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 90, 116, and 104 in the three preceding weeks, slightly rose to 107 in the week under notice; and 32 deaths were attributed to various forms of violence, against 16 and 23 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 630 births and 438 deaths were registered during the week ended Saturday, May 23rd. The annual rate of mortality in these towns, which had steadily declined from 25·3 to 18·2 per 1000 in the four preceding weeks, rose to 18·9 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 20·6 per 1000; in the 97 large English towns the corresponding rate did not exceed 14·5, while in the 16 Scotch towns it was equal to 16·0 per 1000. The annual death-rate last week was equal to 19·3 in Dublin (against 12·7 in London and 17·8 in Glasgow), 17·9 in Belfast, 19·7 in Cork, 16·5 in Londonderry, 24·4 in Limerick, and 19·0 in Waterford, while in the 21 smaller towns the mean rate rose to 19·5 per 1000.

The 438 deaths from all causes were 17 in excess of the number in the previous week, and included 46 which were referred to the principal epidemic diseases, against numbers declining from 75 to 43 in the five preceding weeks. Of these 46 deaths, 18 resulted from measles, 10 from infantile diarrhœal diseases, 7 from whooping-cough, 6 from scarlet fever, and 5 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases last week was equal to 2·0, against corresponding rates of 1·3 and 1·4 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 45, 30, and 21 in the three preceding weeks, further declined to 18 last week, of which 16 occurred in Dublin. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 8, 3, and 9 in the three preceding weeks, were 10 last week, and included 7 in Dublin and 2 in Belfast. The fatal cases of whooping-cough, which had declined from 14 to 8 in the five preceding weeks, were 7 last week, of which 5 were registered in Belfast. The 6 deaths attributed to scarlet fever were 2 above the average in the earlier weeks of the quarter, and comprised 5 in Belfast and 1 in Dublin. The 5 deaths referred to diphtheria, which were all recorded in Dublin, were 3 above the average in the earlier weeks of the quarter. In addition to the above, 5 fatal cases of typhus were registered in Belfast.

The deaths referred to diseases of the respiratory system, which had been 57, 74, and 85 in the three preceding weeks, fell to 79 in the week under notice. Of the 438 deaths from all causes, 153, or 35 per cent., occurred in public institutions and 9 resulted from various forms of violence. The causes of 20, or 4·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1914.

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

VITAL STATISTICS OF LONDON DURING APRIL, 1914.

In the accompanying table will be found complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 6·3 per 1000 of the population, estimated at 4,516,612 persons in the middle of the year; in the three preceding months the rates were 8·3, 8·5, and 7·4 per 1000 respectively. The lowest rates last month were recorded in Chelsea, St. Marylebone, the City of London, Battersea, and Wandsworth; and the highest rates in Holborn, Finsbury, Southwark, Deptford, and Woolwich. Scarlet fever again showed a decreased prevalence as compared with other recent months; this disease was proportionally most prevalent last month in Holborn, Southwark, Lambeth, Deptford, and Woolwich. The Metropolitan Asylums Hospitals contained 2826 scarlet fever patients at the end of last month, against 3543, 3328, and 3138 at the end of the three preceding months; the weekly admissions averaged 312, against 400, 379, and 337 in the three preceding months. Diphtheria was less prevalent than it had been in any of the seven preceding months; among the several metropolitan boroughs the greatest proportional prevalence of this disease last month was recorded in Stoke Newington, Hackney, Bethnal Green, Poplar, Southwark, Deptford, Greenwich, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1225 and 1305 at the end of the two preceding months, declined again to 1121 at the end of last month; the weekly admissions averaged 114, against 153, 166, and 158 in the three preceding months. Enteric fever was rather more prevalent than it had been in the previous month; the greatest proportional prevalence during April was recorded in the City of Westminster, St. Marylebone, St. Pancras, and Lambeth. There were 55 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 65, 82, and 66 at the end of the three preceding months; the weekly admissions averaged 7, against 15 and 6 in the two preceding months. The 28 cases of puerperal fever notified during the month included 4 in Poplar and 2 each in Islington, Hackney, Stepney, Southwark, and Lambeth. Of the 12 cases of cerebro-spinal meningitis, 4 belonged to Southwark; and the only case of poliomyelitis reported occurred in Lambeth.

The mortality statistics relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the population of the several boroughs. During the four weeks ending May 2nd the deaths of 4789 London residents were registered, equal to an annual rate of 13·8 per 1000; in the three preceding months the rates were 18·4, 14·8, and 15·2 per 1000 respectively. The death-rates last month ranged from 9·9 in Lewisham, 10·0 in Wandsworth, 11·4 in Hammersmith, 11·5 in Paddington, and 11·6 in Hampstead, to 17·7 in Shoreditch, 17·8 in Bethnal Green, 18·0 in Stepney, 18·2 in the City of London, 18·5 in Bermondsey, and 19·1 in Finsbury. The 4789 deaths from all causes included 309 which were attributed to the principal infectious diseases; of these, 74 resulted from measles, 19 from scarlet fever, 38 from diphtheria, 106 from whooping-cough, 9 from enteric fever, and 63 from diarrhœa and enteritis among children under two years of age. No death from any of these diseases occurred last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Paddington, Kensington, Hammersmith, the City of Westminster, Hampstead, Stoke Newington, and Lewisham; and the highest rates in Finsbury, Bethnal Green, Stepney, Southwark, and Bermondsey. The 74 fatal cases of measles were 172 below the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Finsbury, Stepney, Poplar, Bermondsey, Battersea, Deptford, and Greenwich. The 19 fatal cases of scarlet fever were slightly in excess of the corrected average, and included 3 in Southwark, 2 in Camberwell, and 2 in Deptford. The 38 deaths from diphtheria were 2 above the corrected average number; this disease was proportionally most fatal last month in Hackney, Shoreditch, Bethnal Green, Poplar, Southwark, Lambeth, and Woolwich. The 105 fatal cases of whooping-cough were 37 below the corrected average number; the highest death-rates from this cause were recorded in St. Pancras, Holborn, Finsbury, Shoreditch, Bethnal Green, Stepney, and Woolwich. The 9 deaths from enteric fever were 3 in excess of the corrected average number, and included 3 in Lambeth and 2 in Stepney. The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in Hackney, Finsbury, Bethnal Green, Southwark, and Bermondsey.

In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was 45·2 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeon: E. G. E. O'Leary to the *Queen*, on recommissioning. Staff-Surgeon: N. J. Roche to the *Sutlej*, for voyage out and home. Surgeon: F. J. D. Twigg to the *Queen*, on recommissioning.

The undermentioned Staff-Surgeons have been promoted to the rank of Fleet-Surgeon in His Majesty's Fleet:—Henry Cadman Whiteside, Robert Lumley Dickinson, Herbert Wells Bayly Shewell, John Martin, Christian Beverley Fairbank, Francis Frederick Lobb, Harold John Chater, Reginald St. George Smallridge Bond, Charles Clarke Macmillan, D.S.O., Fred Claude Bromley Gittings, Ramsey Martyn Richards, Alan Grant Eastment, and George Ernest Duncan (dated May 23rd, 1914).

ROYAL ARMY MEDICAL CORPS.

Major Robert B. Black retires on retired pay (dated May 27th, 1914).

Colonel R. Kirkpatrick, C.M.G., has been appointed Assistant Director of Medical Services to the Presidency Brigade at Calcutta on transfer from Sialkot Cantonment.

Lieutenant-Colonel A. T. J. Lilly has been appointed to officiate as Assistant Director of Medical Services to the Bombay Brigade. Lieutenant-Colonel E. M. Hassard has been granted six months' general leave of absence home from India. Lieutenant-Colonel J. C. Connor has been appointed Deputy Assistant Director of Medical Services on the Headquarter Staff of the Irish Command. Lieutenant-Colonel H. E. Winter has been appointed to hold charge of the Military Hospital at Colaba, Bombay. Lieutenant-Colonel G. H. Hale, D.S.O., has been selected for appointment as Senior Medical Officer at Sialkot Cantonment. Lieutenant-Colonel N. Faichnie has been appointed to the Western Command. Lieutenant-Colonel M. P. C. Holt, D.S.O., has taken over charge of the Cambridge Military Hospital at Aldershot. Lieutenant-Colonel J. W. Bullen has been transferred from the Military Hospital at Sheffield to Strensall. Lieutenant-Colonel T. du B. Whaite has been appointed to hold charge of the Military Hospital at Lahore.

Major V. J. Crawford has been appointed to the Southern Command. Major H. W. H. O'Reilly has joined at Secunderabad. Major H. M. Nicholls has arrived home for duty from India. Major L. W. Harrison has been appointed to the Royal Army Medical College at Grosvenor-road, S.W. Major F. McLennan has taken up duty at Aberdeen. Major J. Poe has joined at Shorncliffe. Major R. McK. Skinner has embarked for India. Major J. D. G. Macpherson has been appointed Deputy Assistant Director of Medical Services to the West Lancashire Division. Major H. D. Packer has joined at Karachi. Major E. F. Q. L'Estrange has arrived home from Cannanore Cantonment. Major A. E. Milner has been appointed to the Recruiting Medical Staff at Birmingham. Major P. S. O'Reilly has been appointed Medical Officer at the Royal Arsenal, Woolwich. Major H. B. G. Walton has been appointed Specialist in the Prevention of Disease to the Bareilly Brigade and placed in charge of the Bacteriological Research Laboratory at the Military Hospital, Bareilly Cantonment. Major C. J. O'Gorman, D.S.O., has been transferred from the Military Hospital at Calcutta to Barrackpore Cantonment. Major G. J. S. Archer has taken up duty at the Royal Victoria Military Hospital, Netley.

Captain H. V. Bagshawe has been transferred from the Military Hospital at Cyprus to Cairo. Captain T. S. Coates has joined at Meerut Cantonment. Captain A. L. Stevenson has been granted six months' general leave of absence home from India. Captain C. W. Bowle has arrived home from India. Captain A. Irvine-Fortescue has taken up special duty in Japan. Captain E. D. Caddell has been appointed to the Dublin District. Captain J. D. Bowie has arrived home on leave of absence. Captain O. R. McEwen has been appointed to the Irish Command. Captain A. H. Hayes has taken up duty at Ambala Cantonment. Captain W. E. C. Lunn has been appointed to the Aldershot Command. Captain V. P. Hutchinson has been appointed to the staff of the Military Hospital at Potchefstroom. Captain T. H. Dickson has taken up duty at Bareilly. Captain R. J. Cahill has been transferred from the Military Hospital at Londonderry to Belfast. Captain M. B. H. Ritchie has been transferred from Chatham to the Colchester District. Captain M. O. Wilson has arrived home from Aden. Captain T. H. Scott has arrived home from India. Captain P. S. Stewart has been appointed to the Southern Command. Captain H. H. Leeson has been appointed to Khartoum. Captain A. C. Elliott has arrived home from the Military Hospital at Sialkot Cantonment. Captain E. B. Lathbury has been appointed to the Irish Command. Captain A. T. Frost has been transferred from the Military Hospital at Lucknow to Poona Cantonment. Captain C. H. O'Rorke has been appointed to the Military Hospital at Darjeeling. Captain A. D. Stirling has joined the Military Hospital at Cairo. Captain J. R. Forster has been appointed to the Dublin District. Captain M. J. Williamson has been appointed to the Military Hospital at Simonstown. Captain E. W. Vaughan has taken up duty in the Devonport District. Captain R. J. B. Buchanan has taken up duty at the Royal Victoria Military Hospital, Netley. Captain H. H. Blake has joined at Peshawar Cantonment. Captain C. E. W. S. Fawcett has taken up duty at the Military Hospital, Secunderabad Cantonment. Captain W. W. Browne has been appointed Specialist in the Prevention of Disease to the Ahmednagar Brigade. Captain R. A. Bryden has joined at Fleetwood. Captain T. W. Browne has been appointed to the Military Hospital at Cork.

Lieutenant T. E. Osmond has been selected for appointment as Specialist in Dermatology and Venereal Diseases to the Eighth (Lucknow) Division of the Northern Army in India. Lieutenant C. M. Finny has been transferred from the Military Hospital at Ambala Cantonment to the Second (Rawal Pindi) Division. Lieutenant W. L. Webster has embarked for Egypt. Lieutenant W. S. R. Steven has been appointed to the Military Hospital at Quetta Cantonment. Lieutenant F. A. Robinson has been transferred from the Military Hospital at Mhow to Nasirabad Cantonment. Lieutenant R. Davidson has been appointed to the Eighth (Lucknow) Division of the Northern Army in India.

INDIAN MEDICAL SERVICE.

Colonel D. St. J. Dundas Grant has been appointed Assistant Director of Medical Services to the Karachi Brigade.
